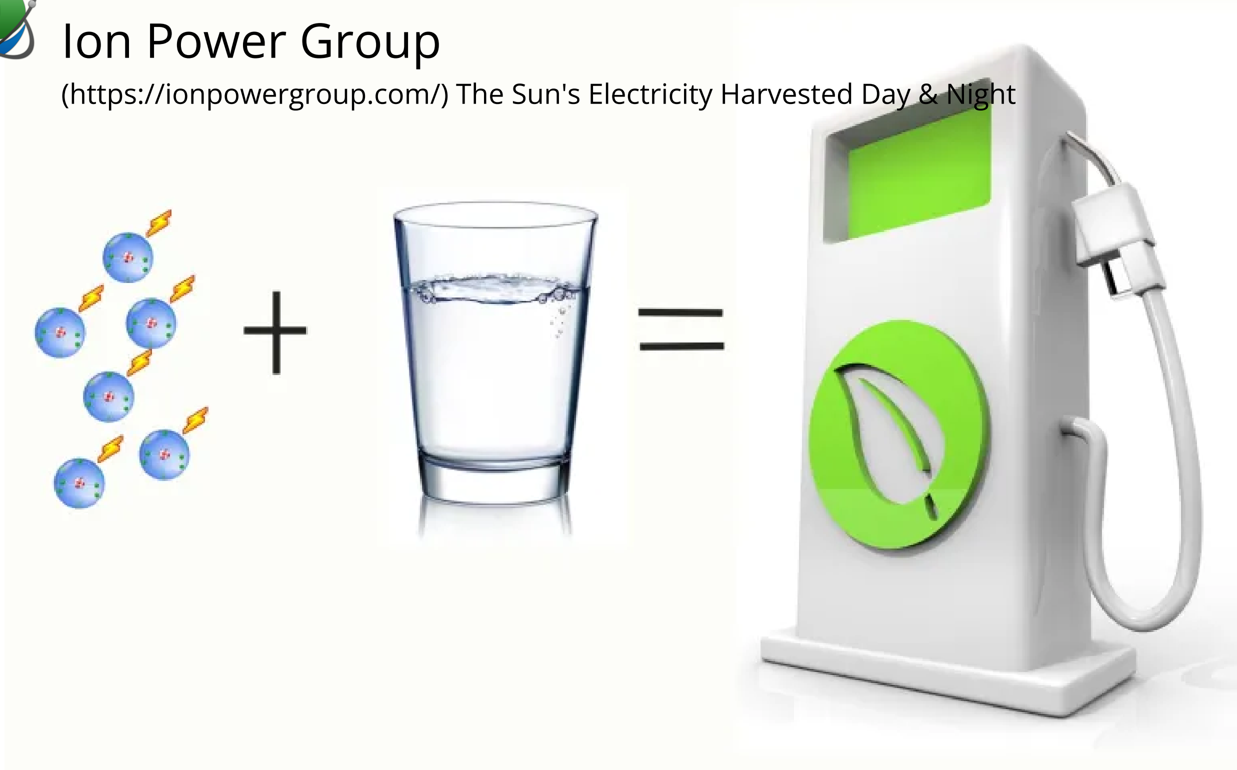
Electricity harvested from Airborne Ions + Water = Hydrogen Gas

TOP



TOP

Ion Power Group has been awarded patents for installing ion collectors on automobiles to generate electricity including through the Triboelectric Effect. Preliminary field tests in which a truck, equipped with Ion Collectors, demonstrated that the concept can generate >500 volts when the vehicle is in motion. Initial tests are encouraging, however, further development is required in order to realize automobiles that generate their own supplemental electricity (or onboard hydrogen gas from water) through use of Ion Collectors.

TOP

Illustrations (below) of proposed experimental ion power plants using long-duration aerostats (aerostats or balloons) or kites or towers to provide altitude to the ion collectors to harvest ions for electricity, day and night. Future Ion Harvesting Technology embodiments that use long-duration aerostats (balloons) to provide great altitude to ion collectors offer a theoretical energy producing duty-cycle approaching 99%.

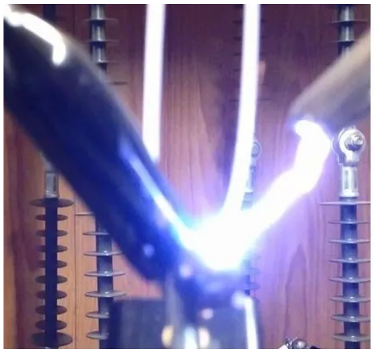
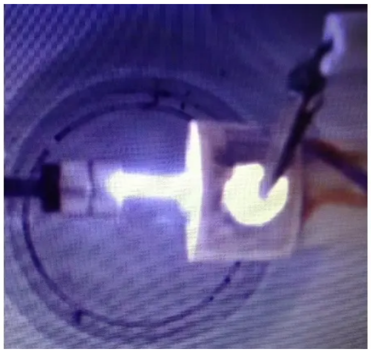
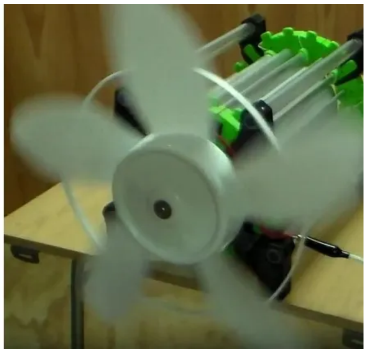
Highly energetic **G**alactic **C**osmic **R**ays (GCRs) arriving from deep space impact Mars' atmosphere on a consistent basis creating electrically charged ions throughout the atmosphere. Carbon/graphite nanomaterials have been shown to be effective at harvesting electricity from atmospheric ions on Earth. Likewise, it is anticipated that carbon nanomaterials elevated into the Martian atmosphere can also harvest electricity from Mars' ion-rich atmosphere day and night and particularly during dust storms.







↑ TOP

On Earth, experiments have demonstrated that high voltage electricity harvested from airborne ions can power lights, motors or produce hydrogen & oxygen gas via water electrolysis or place a charge on lithium-iron (LiFePO4) batteries and be converted to 120VAC/60hZ 'house style' current. Mars has an ion-rich atmosphere believed to be even more advantageous for Ion Harvesting Technology. See 'Concept Clips' for videos.

Space Tech Startups Are The Key To Making Life On Mars Possible

Sep 21, 2018. Compressed screen capture from online FORBES

- **Ion Power Group** — Ion Power Group's technology converts electrically charged ions native to the Martian atmosphere into usable energy. These ions are constantly being created by galactic cosmic rays and are plentiful on Mars, providing a renewable source of electricity for Martian colonists. Despite the many different proposals for power generation on Mars, Ion's solution seems more elegant than—or at least a more elegant companion to—the Kilopower nuclear reactors currently being championed by NASA.

Although public space agencies like NASA and major aerospace companies worldwide continue to be the driving forces behind humanity's journey to Mars, an increasing number of startups like those mentioned here are jumping in to provide critical supporting technologies.

When we do finally put a person on Mars, don't be surprised if many of the machines and devices that make it possible are stamped with company names and logos you've never heard of. Just as it takes hundreds of companies of all sizes to create and maintain our physical infrastructure here on Earth, so too will it take many ideas and many voices to build infrastructure on Mars that supports exploration and, ultimately, habitation.

Dust storms occurring on Mars generate strong electrical fields that propagate throughout the Martian atmosphere conveyed by the ions constantly present in the atmosphere. Dust storms can cover large regions of the planet blotting out the sun and can persist for days or weeks. Because the ion-filled Martian atmosphere is electrically conductive, electricity generated by remote dust storms elsewhere on the planet is permitted to propagate throughout the Martian atmosphere. NASA Scientist, Michael Smith, who works at the NASA Goddard Space Flight Center told Space.com "***The dust is electrostatic, like foam peanuts.***" In an interview with NewScientist.com, Brian Jackson with the Physics

Ion collectors composed of Graphite and/or Graphene, while not metalic, are electrically conductive, flexible and durable. Electric fields are attracted to conductive points, known as the ‘Corona Effect’. Ion collectors offer millions of microscopic electrically conductive points and protrusions which readily couple to the electric fields of nearby ions transferring high voltage electricity from the atmospheric ions to the ion collectors. Measurements have shown that ion collectors made of graphite are more efficient at harvesting electricity from airborne ions than tested metals. In some tests, by as much as

TOP

55x greater efficiency. Some of the tested metals include highly conductive silver, copper, and aluminum wire – aluminum spheres – copper and aluminum sheets.

Ion Power Group's internationally patented ion collectors, elevated between two poles in the below depiction, are specially designed to couple to the energetic electrically charged ions in the Martian atmosphere. Ion collectors are designed to harvest the high voltage DC electric charge from naturally occurring atmospheric ions day and night and during dust storms and are not dependent on sun or wind. Ground based circuitry has been designed to maintain the ion collector material at a voltage considerably lower than the surrounding atmospheric ions thereby employing the electrostatic attraction principle causing nearby ions to migrate to the ion collectors. Wires will convey the harvested electricity to the base camp where it is routed to a storage medium (such as super capacitors, graphene batteries, lithium-ion batteries, hydrogen gas fuel cells) to be used for life support, light, heat, the production of oxygen for breathing and rocket fuel (hydrogen) from Martian water, communications, fisheries, agriculture and transportation.

Three tethered aerostats (specially sized for the Martian atmosphere) equipped with Ion Harvesting Technology could generate up to 60kW of electricity on Mars.

TOP

"Solar power… cannot be used at night and during dust storms. It has been shown (in the Power to Mars technical report) that ion power and solar power can be combined to provide a reliable and safe power generation concept." **PhD Atmospheric Physicist and Senior Scientist with the German Aerospace Center, Dr. Andreas J .G. Baumgaertner**

The conditions on Mars including a weak magnetic field, frequent dust storms around the planet and constant bombardment of the Martian atmosphere by GCRs provide an ideal electrical environment for Ion Power Group technology to harvest the electric charge of naturally occurring atmospheric ions to produce reliable, environmentally friendly, electrical power without reliance on sunlight, wind, nuclear or fossil fuels. The highly ionized Martian atmosphere will provide an extremely fertile electrical environment for Ion Power Group's technology to generate clean renewable pollution-free electrical energy day and night and during dust storms. The ability of ion harvesting to generate electricity day/night/dust storms will prove valuable to power robots, rovers, drones, vehicles, living quarters, lights, communications, entertainment equipment, heat to melt Martian ice for drinking, trenchers for extracting

water from soil, water for agriculture and fisheries as well as producing hydrogen gas to use for rocket fuel and oxygen for breathing through electrolysis of Martian water.

Nearly 100 countries have some level of space program. A growing number of governments, as well as many private and corporate organizations, are developing plans to send robots and hardware to be followed by people to colonize Mars in the foreseeable future. All of these campaigns will require a reliable source of electrical power on the surface of Mars.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support system. The support system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but graphene, carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS-REFERENCE TO RELATED APPLICATION

[0001] This application is a continuation of U.S. utility patent application Ser. No. 14/454,308, filed on Aug. 7, 2014, which is incorporated by reference herein.

TECHNICAL FIELD

[0002] The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

[0003] The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

[0004] In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

[0005] Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

[0006] Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

[0007] While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

[0008] Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level; at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment electrically connected to the support structure; and a load electrically connected to the at least one collection device.

[0009] Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment from a support structure, the at least one collection device electrically connected to the support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level; and providing a load with an electrical connection to the at least one collection device to draw current.

[0010] Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

[0017] FIG. **2**D is a side view of an example embodiment of a support structure for multiple energy collection fibers.

[0018] FIG. **2**E is a side view of a support structure for an energy collection fiber.

[0019] FIG. **2**F is a side view of an example embodiment of a support structure for an energy collection fiber.

[0020] FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

[0021] FIG. **3** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

[0022] FIG. **4** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

[0023] FIG. **5** is a circuit diagram of an example embodiment of an energy collection circuit for powering a generator and motor.

[0024] FIG. **6** is a circuit diagram of an example embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

[0025] FIG. **7** is a circuit diagram of an example embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

[0026] FIG. **8** is a circuit diagram of an example embodiment of a circuit for collecting energy.

[0027] FIG. **9** is a flow diagram of an example embodiment of collecting energy with a collection fiber.

[0028] FIG. **10** is a circuit diagram of an example embodiment of a circuit for collecting energy from a dual polarity source.

[0029] FIG. **11** is a system diagram of an example embodiment of an energy collection system connected to an automobile vehicle.

[0030] FIG. **12** is a system diagram of an example embodiment of an energy collection system connected to a lunar rover vehicle.

[0031] FIG. **13** is a system diagram of an example embodiment of an energy collection system comprising collection devices with a diode.

[0032] FIG. **14** is a system diagram of an example embodiment of an energy collection system comprising multiple legs of the system of FIG. **13**.

[0033] FIG. **15** is a system diagram of an example embodiment of a windmill with energy collectors.

DETAILED DESCRIPTION

[0034] Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An example embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An example embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

[0035] An example embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate collection ability.

[0036] In at least one example embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than **100** volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

[0037] A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An example embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

[0038] Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2**A-**2**G using a collection fiber embodiment. FIG. **2**A presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

[0039] Likewise, FIG. **2**B shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

[0040] FIG. 2C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

[0041] FIG. 2D presents another example embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0042] FIG. 2E provides another example embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

[0043] FIG. 2F presents another example embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0044] FIG. 2G provides two supports as provided in FIG. 2F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

[0045] FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** maybe connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

[0046] In an example embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

[0047] FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

[0048] FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes maybe placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

[0049] FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

[0050] FIG. **8** presents example circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820**

may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

[0051] FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

[0052] FIG. **10** presents circuit **1000** as an example embodiment for the collection of energy from a dual polarity source. This may be used, for example, to collect atmospheric energy that reverses in polarity compared with the ground. Such polarity reversal has been discovered as occurring occasionally on Earth during, for example, thunderstorms and bad weather, but has also been observed during good weather. Such polarity reversal may occur on other planetary bodies, including Mars and Venus, as well. Energy polarity on other planets, in deep space, or on other heavenly bodies, may be predominantly negative or predominantly positive. Collector fibers (**130** from FIG. **2**), which may comprise graphene, silicene, and/or other like materials, are capable of collecting positive energy and/or negative energy, and circuit **1000** is capable of processing positive and/or negative energy, providing an output which is always positive. Circuit **1000** may collect energy from one or more collection devices (**130** from FIG. **2**). Charging capacitor **1010** may be used to store a charge until the voltage at spark gap **1020** achieves the spark voltage. Capacitor **1010** is optional.

[0053] A plurality of diodes may be placed in a plurality of positions in circuit **1000**. The voltage from capacitor **1010** may be used to charge spark gap **1020** to a sufficient voltage. Spark gap **1020** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **1020** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **1020** arcs, energy will arc from an emitting end of spark gap **1020** to a receiving end of spark gap **1020**. The output of spark gap **1020** is electrically connected to the anode of diode **1022** and the cathode of diode **1024**. The cathode of diode **1022** is electrically connected to the cathode of diode **1026** and inductor **1030**. Inductor **1030** may be a fixed value inductor or a variable inductor. The anode of diode **1026** is electrically connected to ground. Capacitor **1028** is electrically connected between ground and the junction of the cathodes of diode **1022** and diode **1026**. Inductor **1035** is electrically connected between ground and the anode of diode **1024**. Inductor **1035** may be a fixed value inductor or a variable inductor. Capacitor **1070**, the anode of diode **1026**, inductor **1035**, and load **1050** are electrically connected to ground. Capacitor **1070** may be placed in parallel with load **150**.

[0054] FIGS. **11** and **12** provide example embodiments of vehicle **1110**, which utilizes electricity, the vehicle employing systems of energy collection provided herein. Vehicle **1100** in FIG. **11** is shown as an automobile vehicle, but could be any means of locomotion that utilizes electricity, including a car, a train, a motorcycle, a boat, an airplane, robotic rovers, space craft, etc. Vehicle **1200** in FIG. **12** is shown as a lunar rover vehicle. In FIGS. **11** and **12**, support rod **1110**, **1210** is electrically connected to an electrical system in vehicle **1100**, **1200**. Energy collectors **130**, which may comprise graphene, silicene, and/or other like materials, are electrically connected to support rod **1110**, **1210** and may be used to supply energy to electrical circuits within the vehicle. A non-limiting use includes a top-off charge for a battery system, on-board hydrogen production, and/or assisting in the same. Energy collectors **130** may be used to augment the efficiency of the locomotion that utilizes electrical energy as well.

[0055] FIG. **13** provides an example embodiment of energy collection system **1200** in which diode **310** is used to isolate collection devices **130** from spark gap **1020** and load **150**. Collection devices **130** may comprise graphite, carbon fibers, carbon/carbon fibers, graphene, silicene, and/or other like materials, or a mixture thereof.

[0056] FIG. **14** provides an example embodiment of energy collection system **1400** in which a plurality of energy collection systems, such as that provided in FIG. **13**, are combined. Each leg consisting of collection devices **130**, which may comprise graphene, silicene, and/or other like materials, and diode **310** are connected in parallel with other legs, each leg electrically connected to trunk wire **1410**. The legs could also be connected serially. Trunk wire **1410** is electrically connected to a collection circuit, which may comprise load **150** and spark gap **1020** in any configuration that has been previously discussed. Each leg may comprise one or more collection devices **130** and at least one diode electrically connected between the collection devices and the collection circuit. Although three collection devices **130** are shown on each leg, any number of collection devices may be used. Although four legs are shown, any number of legs may be used.

[0057] FIG. **15** presents a system diagram of an example embodiment of a windmill with energy collectors, which may comprise graphene, silicene, and/or other like materials in an example embodiment. A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1500** of suitable height and/or propeller **1520** of windmill tower **1500** may be equipped with energy collecting fibers **1530**, **1540**, which may comprise graphene, silicene, and/or other like materials in an example embodiment. Collecting fibers **1530**, **1540** may turn windmill **1500** into a power producing asset even when there is not enough wind to turn propellers **1520**. During periods when there is enough wind to turn propellers **1520**, collecting fibers **1530**, **1540** may supplement/boost the amount of energy the windmill produces.

[0058] A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1000** of suitable height and/or propeller **1020** of windmill tower **1000** may be equipped with energy collecting fibers **1030**, **1040**. Collecting fibers **1030**, **1040** may turn windmill **1000** into a power producing asset even when there is not enough wind to turn propellers **1020**. During periods when there is enough wind to turn propellers **1020**, collecting fibers **1030**, **1040** may supplement/boost the amount of energy the windmill produces.

[0059] Windmill **1500**, properly equipped with ion collectors **1530**, **1540**, such as a non-limiting example of fibers with graphene, silicene, and/or other like materials, can produce electricity: 1) by virtue of providing altitude to the fiber to harvest ions, and 2) while the propeller is turning, by virtue of wind blowing over the fiber producing electricity, among other reasons, via the triboelectric effect (however, it is also possible for the triboelectric effect to occur, producing electricity, in winds too weak to turn the propeller).

[0060] There are at least two ways that energy collectors may be employed on or in a windmill propeller to harvest energy. Propellers **1520** may be equipped with energy collectors **1530**, **1540** attached to, or supported by, propeller **1520** with wires (or metal embedded in, or on propeller **1520**) electrically connecting energy collectors **1530**, **1540**, which may comprise graphene, silicene, and/or other like materials, to a load or power conversion circuit. There may be a requirement to electrically isolate energy collectors **1530**, **1540**, which are added to propeller **1520**, from electrical ground, so that the energy collected does not short to ground through propeller **1520** itself or through support tower **1510**, but rather is conveyed to the load or power conversion circuit. Energy collectors may be connected to the end of propellers **1520** such as collectors **1530**. Alternatively, energy collectors may be connected to the sides of propellers **1520** such as collectors **1540**.

[0061] Alternatively, propeller **1520** may be constructed of carbon fiber or other suitable material, with wires (or the structural metal supporting propeller **1520** may be used) electrically connecting to a load or power conversion circuit. In the case of propeller **1520** itself being constructed of carbon fiber, for example, the fiber may be ‘rough finished’ in selected areas so that the fiber is “fuzzy.” For example, small portions of it may protrude into the air as a means of enhancing collection efficiency. The fuzzy parts of collectors **1530**, **1540** may do much of the collecting. There may be a requirement to electrically isolate carbon fiber propeller **1520** from electrical ground, so that the energy it collects does not short to ground through metal support tower **1510**, but rather is conveyed to the load or power conversion circuit. Diodes may be implemented within the circuit to prevent the backflow of energy, although diodes may not be necessary in some applications.

[0062] In an alternative embodiment, windmill **1500** may be used as a base on which to secure an even higher extension tower to support the energy collectors and/or horizontal supports extending out from tower **1510** to support the energy collectors. Electrical energy may be generated via ion collection due to altitude and also when a breeze or wind blows over the collectors supported by tower **1510**.

[0063] In alternative embodiments to windmill **1500**, other non-limiting example support structures include airplanes, drones, blimps, balloons, kites, satellites, cars, boats, trucks, (including automobile and other transportation conveyance tires), trains, motorcycles, bikes, skateboards, scooters, hovercraft (automobiles and conveyance of any kind), billboards, cell towers, radio towers, camera towers, flag poles, towers of any kind including telescopic, light poles, utility poles, water towers, buildings, sky scrapers, coliseums, roof tops, solar panel and all fixed or mobile structures exceeding 1 inch in height above ground or sea level.

[0064] An example embodiment of a support structure may also include cell phones and other electronic devices and their cases, including cases containing rechargeable batteries. For example, someone may set her cell phone or other electronic device or battery pack on the window ledge of a tall apartment building to help charge it. Other example support structures may include space stations, moon and Mars structures, rockets, planetary rovers and drones including robots and artificial intelligence entities.

[0065] Under some conditions, ambient voltage may be found to be 180-400 volts at around 6 ft, with low current. With the new generation of low current devices being developed, a hat containing ion harvesting material may provide enough charge, or supplemental charge, collected over time to help power low current devices such as future cell phones, tracking devices, GPS, audio devices, smart glasses, etc. Clothes may also be included as examples of support structures. Friction of the ion collection material (such as non-limiting examples of carbon, graphite, silicene and graphene) against unlike materials, such as wool, polyester, cotton, etc (used in clothes) may cause a voltage to be generated when rubbed together. Additionally, wind passing over the ion collection material has been demonstrated to generate voltage, even at low altitude. In an additional example embodiment, embedding collection devices into automobile tires (for example, in a particular pattern) could generate collectible voltage.

[0066] Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

[0067] It should be emphasized that the above-described embodiments of the present disclosure, particularly, any “preferred” embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

1. A method of collecting energy comprising:

suspending at least one graphene collection device, electrically connected to the support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level; and

providing a load with an electrical connection to the at least one collection device to draw current.

2. The method of claim **1**, wherein the graphene collection device collects energy by triboelectric effect.

3. The method of claim **1**, wherein the graphene collection device comprises a graphene mesh.

4. The method of claim **1**, wherein the graphene collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, further comprising a fuel cell for producing hydrogen from the collected energy.

8. A system of energy collection comprising:

a support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level;

at least one graphene collection device electrically connected to the support structure; and

a load electrically connected to the at least one collection device.

9. The system of claim **8**, wherein the graphene collection device collects energy by triboelectric effect.

10. The system of claim **8**, wherein the graphene collection device comprises a graphene mesh.

11. The system of claim **8**, wherein the graphene collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **11**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the support structure comprises a vehicle.

14. The system of claim **8**, further comprising a diode electrically connected between the at least one graphene collection device and the support structure.

15. The system of claim **8**, further comprising: a switch connected in series between the at least one graphene collection device and the load; and a capacitor connected in parallel with the switch and the load.

16. The system of claim **15**, wherein the switch comprises an interrupter connected between the load and at least one graphene collection device, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

17. The system of claim **8**, further comprising: a motor for providing power, the motor connected between the at least one graphene collection device and the load; and a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one graphene collection device, the at least one graphene collection device electrically connected to the means for suspending; and

means for inducing current flow, the means for inducing current flow electrically connected to the graphene collection device.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more

around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected

to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the support structure;

providing a load with an electrical connection to the at least one collection device to passively draw current; and

powering a fuel cell between the support structure and the load, the powering performed with energy collected from the at least one collection device.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a diode electrically connected between the at least one collection device and the support structure.

9. The system of claim **8**, wherein the collection device comprises a diode.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising:

a switch connected in series between the at least one collection device and the load; and

a capacitor connected in parallel with the switch and the load.

15. The system of claim **14**, wherein the switch comprises an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

16. The system of claim **15**, further comprising a transformer connected between the interrupter and the load.

17. The system of claim **8**, further comprising:

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending;

means for passively inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

21. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a switch connected in series between the at least one collection device and the load, the switch comprising an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

22. The system of claim **21**, further comprising a transformer connected between the interrupter and the load.

23. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure, the collection device configured to passively draw current;

a load electrically connected to the at least one collection device;

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

24. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a fuel cell between the support structure and the load.

25. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more

around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected

to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the support structure;

providing a load with an electrical connection to the at least one collection device to passively draw current; and

powering a fuel cell between the support structure and the load, the powering performed with energy collected from the at least one collection device.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a diode electrically connected between the at least one collection device and the support structure.

9. The system of claim **8**, wherein the collection device comprises a diode.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising:

a switch connected in series between the at least one collection device and the load; and

a capacitor connected in parallel with the switch and the load.

15. The system of claim **14**, wherein the switch comprises an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

16. The system of claim **15**, further comprising a transformer connected between the interrupter and the load.

17. The system of claim **8**, further comprising:

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending;

means for passively inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

21. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a switch connected in series between the at least one collection device and the load, the switch comprising an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

22. The system of claim **21**, further comprising a transformer connected between the interrupter and the load.

23. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure, the collection device configured to passively draw current;

a load electrically connected to the at least one collection device;

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

24. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a fuel cell between the support structure and the load.

25. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

UNITED STATES PATENT OFFICE.

NIKOLA TESLA, OF NEW YORK, N. Y.

METHOD OF UTILIZING RADIANT ENERGY.

SPECIFICATION forming part of Letters Patent No. 685,958, dated November 5, 1901.

Application filed March 21, 1901. Serial No. 52,154. (No model.)

To all whom it may concern:

Be it known that I, NIKOLA TESLA, a citizen of the United States, residing at the borough of Manhattan, in the city, county, and State of New York, have invented certain new and useful Improvements in Methods of Utilizing Radiant Energy, of which the following is a specification, reference being had to the drawings accompanying and forming a part of the same.

It is well known that certain radiations—such as those of ultra-violet light, cathodic, Roentgen rays, or the like—possess the property of charging and discharging conductors of electricity, the discharge being particularly noticeable when the conductor upon which the rays impinge is negatively electrified. These radiations are generally considered to be ether vibrations of extremely small wave lengths, and in explanation of the phenomena noted it has been assumed by some authorities that they ionize or render conducting the atmosphere through which they are propagated. My own experiments and observations, however, lead me to conclusions more in accord with the theory heretofore advanced by me that sources of such radiant energy throw off with great velocity minute particles of matter which are strongly electrified, and therefore capable of charging an electrical conductor, or even if not so may at any rate discharge an electrified conductor either by carrying off bodily its charge or otherwise.

My present application is based upon a discovery which I have made that when rays or radiations of the above kind are permitted to fall upon an insulated conducting body connected to one of the terminals of a condenser, while the other terminal of the same is made by independent means to receive or to carry away electricity, a current flows into the condenser so long as the insulated body is exposed to the rays, and under the conditions hereinafter specified an indefinite accumulation of electrical energy in the condenser takes place. This energy after a suitable time interval, during which the rays are allowed to act, may manifest itself in a powerful discharge, which may be utilized for the operation or control of mechanical or electrical devices or rendered useful in many other ways.

In applying my discovery I provide a condenser, preferably of considerable electrostatic capacity, and connect one of its terminals to an insulated metal plate or other conducting body exposed to the rays or streams of radiant matter. It is very important, particularly in view of the fact that electrical energy is generally supplied at a very slow rate to the condenser, to construct the same with the greatest care. I use by preference the best quality of mica as dielectric, taking every possible precaution in insulating the armatures, so that the instrument may withstand great electrical pressures without leaking and may leave no perceptible electrification when discharging instantaneously. In practice I have found that the best results are obtained with condensers treated in the manner described in a patent granted to me February 23, 1897, No. 577,671. Obviously the above precautions should be the more rigorously observed the slower the rate of charging and the smaller the time interval during which the energy is allowed to accumulate in the condenser. The insulated plate or conducting body should present as large a surface as practicable to the rays or streams of matter, I having ascertained that the amount of energy conveyed to it per unit of time is under otherwise identical conditions proportionate to the area exposed, or nearly so. Furthermore, the surface should be clean and preferably highly polished or amalgamated. The second terminal or armature of the condenser may be connected to one of the poles of a battery or other source of electricity or to any conducting body or object whatever of such properties or so conditioned that by its means electricity of the required sign will be supplied to the terminal. A simple way of supplying positive or negative electricity to the terminal is to connect the same either to an insulated conductor, supported at some height in the atmosphere, or to a grounded conductor, the former, as is well known, furnishing positive and the latter negative electricity. As the rays or supposed streams of matter generally convey a positive charge to the first condenser-terminal, which is connect-

262 RADIANT ENERGY.

EXAMINER

ed to the plate or conductor above mentioned, I usually connect the second terminal of the condenser to the ground, this being the most convenient way of obtaining negative electricity, dispensing with the necessity of providing an artificial source. In order to utilize for any useful purpose the energy accumulated in the condenser, I furthermore connect to the terminals of the same a circuit including an instrument or apparatus which it is desired to operate and another instrument or device for alternately closing and opening the circuit. This latter may be any form of circuit-controller, with fixed or movable parts or electrodes, which may be actuated either by the stored energy or by independent means.

The rays or radiations which are to be utilized for the operation of the apparatus above described in general terms may be derived from a natural source, as the sun, or may be artificially produced by such means, for example, as an arc-lamp, a Roentgen tube, and the like, and they may be employed for a great variety of useful purposes.

My discovery will be more fully understood from the following detailed description and annexed drawings, to which reference is now made, and in which—

Figure 1 is a diagram showing typical forms of the devices or elements as arranged and connected in applying the method for the operation of a mechanical contrivance or instrument solely by the energy stored; and Fig. 2 is a diagrammatical representation of a modified arrangement suitable for special purposes, with a circuit-controller actuated by independent means.

Referring to Fig. 1, C is the condenser, P the insulated plate or conducting body, which is exposed to the rays, and P′ another plate or conductor, all being joined in series, as shown. The terminals T T′ of the condenser are also connected to a circuit including a receiver R, which is to be operated, and a circuit-controlling device *d*, which in this case is composed of two very thin conducting-plates *t t′*, placed in close proximity and very mobile, either by reason of extreme flexibility or owing to the charater of their support. To improve their action, they should be inclosed in a receptacle from which the air may be exhausted. The receiver R is shown as consisting of an electromagnet M, a movable armature *a*, a retractile spring *b*, and a ratchet-wheel *w*, provided with a spring-pawl *r*, which is pivoted to armature *a*, as illustrated. The apparatus being arranged as shown, it will be found that when the radiations of the sun or of any other source capable of producing the effects before described fall upon the plate P an accumulation of electrical energy in the condenser C will result. This phenomenon, I believe, is best explained as follows: The sun as well as other sources of radiant energy throw off minute particles of matter positively electrified, which, impinging upon the plate P, communicate an electrical charge to the same. The opposite terminal of the condenser being connected to the ground, which may be considered as a vast reservoir of negative electricity, a feeble current flows continuously into the condenser, and inasmuch as these supposed particles are of an inconceivably small radius or curvature, and consequently charged to a relatively very high potential, this charging of the condenser may continue, as I have found in practice, almost indefinitely, even to the point of rupturing the dielectric. Obviously whatever circuit-controller be employed it should operate to close the circuit in which it is included when the potential in the condenser has reached the desired magnitude. Thus in Fig. 2 when the electrical pressure at the terminals T T′ rises to a certain predetermined value the plates *t t′*, attracting each other, close the circuit connected to the terminals. This permits a flow of current which energizes the magnet M, causing it to draw down the armature *a* and impart a partial rotation to the ratchet-wheel *w*. As the current ceases the armature is retracted by the spring *b* without, however, moving the wheel *w*. With the stoppage of the current the plates *t t′* cease to be attracted and separate, thus restoring the circuit to its original condition.

Many useful applications of this method of utilizing the radiations emanating from the sun or other source and many ways of carrying out the same will at once suggest themselves from the above description. By way of illustration a modified arrangement is shown in Fig. 2, in which the source S of radiant energy is a special form of Roentgen tube devised by me having but one terminal *k*, generally of aluminium, in the form of half a sphere with a plain polished surface on the front side, from which the streams are thrown off. It may be excited by attaching it to one of the terminals of any generator of sufficiently-high electromotive force; but whatever apparatus be used it is important that the tube be exhausted to a high degree, as otherwise it might prove entirely ineffective. The working or discharge circuit connected to the terminals T T′ of the condenser includes in this case the primary *p* of a transformer and a circuit-controller comprising a fixed terminal or brush *t* and a movable terminal *t′* in the shape of a wheel with conducting and insulating segments which may be rotated at an arbitrary speed by any suitable means. In inductive relation to the primary wire or coil *p* is a secondary *s*, usually of a much greater number of turns, to the ends of which is connected a receiver R. The terminals of the condenser being connected as indicated, one to an insulated plate P and the other to a grounded plate P′, when the tube S is excited rays or streams of matter are emitted from the same, which convey a positive charge to the plate P and condenser-terminal T, while terminal T′ is continuously receiving negative electricity from the plate

P′. This, as before explained, results in an accumulation of electrical energy in the condenser, which goes on as long as the circuit including the primary p is interrupted. Whenever the circuit is closed, owing to the rotation of the terminal t', the stored energy is discharged through the primary p, this giving rise in the secondary s to induced currents which operate the receiver R.

It is clear from what has been stated above that if the terminal T′ is connected to a plate supplying positive instead of negative electricity the rays should convey negative electricity to plate P. The source S may be any form of Roentgen or Lenard tube; but it is obvious from the theory of action that in order to be very effective the electrical impulses exciting it should be wholly or at least preponderatingly of one sign. If ordinary symmetrical alternating currents are employed, provision should be made for allowing the rays to fall upon the plate P only during those periods when they are productive of the desired result. Evidently if the radiations of the source be stopped or intercepted or their intensity varied in any manner, as by periodically interrupting or rythmically varying the current exciting the source, there will be corresponding changes in the action upon the receiver R, and thus signals may be transmitted and many other useful effects produced. Furthermore, it will be understood that any form of circuit-closer which will respond to or be set in operation when a predetermined amount of energy is stored in the condenser may be used in lieu of the device specifically described with reference to Fig. 1, and also that the special details of construction and arrangement of the several parts of the apparatus may be very greatly varied without departure from the invention.

Having described my invention, what I claim is—

1. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other armature by independent means, and discharging the condenser through a suitable receiver, as set forth.

2. The method of utilizing radiant energy, which consists in simultaneously charging a condenser by means of rays or radiations and an independent source of electrical energy, and discharging the condenser through a suitable receiver, as set forth.

3. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other by independent means, controlling the action or effect of said rays or radiations and discharging the condenser through a suitable receiver, as set forth.

4. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations and the other by independent means, varying the intensity of the said rays or radiations and periodically discharging the condenser through a suitable receiver, as set forth.

5. The method of utilizing radiant energy, which consists in directing upon an elevated conductor, connected to one of the armatures of a condenser, rays or radiations capable of positively electrifying the same, carrying off electricity from the other armature by connecting the same with the ground, and discharging the accumulated energy through a suitable receiver, as set forth.

6. The method of utilizing radiant energy, which consists in charging one of the armatures of a condenser by rays or radiations, and the other by independent means, and effecting by the automatic discharge of the accumulated energy the operation or control of a suitable receiver, as set forth.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this

property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than **100** volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**.

Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be

placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load.

Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground.

The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device from a plurality of support structure wires elevated above a ground level, the collection device including a carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the support structure wire; and

providing a load with an electrical connection to the plurality of support structure wires to draw current.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a diode electrically connected between the fiber and the load.

4. The method of claim **1**, further comprising storing energy provided to the load.

5. The method of claim **4**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

6. The method of claim **2**, wherein the diode is elevated relative to the ground level.

7. A system of energy collection comprising:

a plurality of support structure wires elevated above ground level; at least one collection device including at least one carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the plurality of support structure wires; and

a load electrically connected to the plurality of support structure wires.

8. The system of claim **7**, wherein the collection device comprises a diode.

9. The system of claim **7**, wherein the collection device comprises a diode electrically connected between the load and the fiber.

10. The system of claim **8**, wherein the diode is elevated relative to the ground level.

11. The system of claim **7**, further comprising a diode electrically connected between the at least one collection device and the plurality of support structure wires.

12. The system of claim **7**, wherein the fiber comprises a first end and a second opposing end, and wherein the system further comprises a support structure connected to both ends of the fiber.

13. The system of claim **7**, comprising:

said at least one fiber including a plurality of collection fibers; a support frame having a top side and a bottom side; and a conducting connecting wire between the plurality of support structure wires and the support frame, wherein one end of each of a plurality of collection fibers is connected to the top side of the support frame, and the opposing end of each of a plurality of collection fibers is connected to the bottom side of the support frame.

14. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from a single point of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

15. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from multiple points of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

16. The system of claim **14**, further comprising a plurality of rigid structures wherein said at least one fiber includes collection fibers connected between a plurality of the rigid structures.

17. The system of claim **7**, further comprising:

a switch connected in series between the plurality of support structure wires and the load; and

a capacitor connected in parallel with the switch and the load.

18. The system of claim **17**, wherein the switch comprises an interrupter connected between the plurality of support structure wires and the load.

19. The system of claim **18**, wherein the interrupter comprises one of a fluorescent tube, a neon bulb, an AC light, or a spark gap.

20. The system of claim **18**, further comprising a transformer connected between the interrupter and the load.

21. The system of claim **7**, further comprising:

a motor for providing power the motor connected between the plurality of support structure wires and the load; and

a generator powered by the motor.

22. The system of claim **7**, wherein the load comprises a spark gap in a container of fluid, and the load is used to produce a chemical reaction.

23. The system of claim **22**, wherein the fluid comprises water and the chemical reaction comprises the production of hydrogen and oxygen.

24. The system of claim **7**, further comprising a fuel cell between the plurality of support structure wires and the load.

25. The system of claim **7**, wherein the load comprises a fuel cell.

26. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

27. The system of claim **24**, further comprising a diode connected between the plurality of support structure wires and the fuel cell.

28. A system of collecting energy comprising:

means for suspending carbon or graphite collection fibers, the means elevated above a ground level, the collection fibers collecting electrical enemy from the air and electrically connected to the means for suspending collection fibers;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending collection fibers; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the collection fibers and the means for inducing current flow.

(57) ABSTRACT

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon, graphite, carbon/carbon, or a mixture thereof are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation-in-part application of U.S. patent application Ser. No. 11/358,264,filed on Feb. 21, 2006,which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air or other gases. On Earth, clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the Earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the Earth's atmosphere or above the surface or in the atmosphere of other planets may include cosmic rays penetrating and interacting with the planet's surface and/or atmosphere, and also the creation and migration of electrically charged ions, as well as other effects yet to be fully studied.

Some of the ionization near the surface of a planet or in the lower atmosphere is caused by airborne radioactive substances. In most places on Earth, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are also responsible for atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere of Earth, as well as above the surface or in the atmosphere of other bodies in space, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an example embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an example embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an example embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an example embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an example embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an example embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an example embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an example embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an example embodiment of collecting energy with a collection fiber.

FIG. **10** is a circuit diagram of an example embodiment of a circuit for collecting energy from a dual polarity source.

FIG. **11** is a system diagram of an example embodiment of an energy collection system connected to an automobile vehicle.

FIG. **12** is a system diagram of an example embodiment of an energy collection system connected to a lunar rover vehicle.

FIG. **13** is a system diagram of an example embodiment of an energy collection system comprising collection devices with a diode.

FIG. **14** is a system diagram of an example embodiment of an energy collection system comprising multiple legs of the system of FIG. **13**.

DETAILED DESCRIPTION

Methods for collecting ambient energy have been known since the early 1900's. However, due to low efficiency, those methods did not become commercially feasible. One of the primary advantages of the present disclosure over past arts is the efficiency achievable by utilizing the collection fibers disclosed herein to collect or harvest said ambient energy. Another primary advantage over past arts is the dual-polarity circuit (FIG. **10**) which makes use of both positive and negative ambient energy collected by the collection fibers to convert said energy into a steady positive electrical output.

Electric charges on conductors may reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An example embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere or above the surface of a planet or heavenly body. "Energy" is not limited herein to energy generated by an electric field in the atmosphere. Energy as used herein may include any event, particle, or wave, including, but not limited to photons, protons, neutrons, electrons, neutrinos, leptons, muons, antimuons, mesons, baryons, positrons, bosons, gluons, gravitons, fermions, hadrons, ionic energy, gamma rays, cosmic rays, solar wind, quarks, energy generated by the triboelectric effect, convection lightning, and many other forms of energy known to one of ordinary skill in the art. These forms of energy, as well as others, may be present not only on Earth, but also on the moon of the Earth, on Mars, on Venus, and on other heavenly bodies and even in the relative vacuum of deep space.

Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An example embodiment utilizes carbon fibers, graphite fibers, carbon/carbon fibers, or a mixture thereof for energy collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including, but not limited to, aluminum, steel, copper, and super-conductive material. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire.

Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An example embodiment of the collection fibers as collection device **130** includes graphite, carbon fibers, carbon/carbon fibers, or a mixture thereof. Graphite, carbon fibers, and carbon/carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity, energetic particles, or waves may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, graphite fibers, carbon/carbon fibers, or a mixture thereof are examples that demonstrate example collection ability.

In at least one example embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100-300 volts per meter under some conditions on Earth. When support wire **120** is suspended at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An example embodiment of the collection device comprises the diode with no collection fiber. Another embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restrict energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. One embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**. In an alternative embodiment, a diode is not placed between collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting.

A plurality of diodes may be placed at any position on the support structure wire. One embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**. In an alternative embodiment, a diode is not placed between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2**C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2**D presents another example embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2**E provides another example embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. One embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**. In an alternative embodiment, one or more diodes are not placed at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2**F presents another example embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2**G provides two supports as provided in FIG. **2**F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and/or between multiple support structures. A plurality of diodes may be placed at any position on the support structure. One embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**. In an alternative embodiment, one or more diodes are not placed at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an example embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **420** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel or as components for breathable air, among other uses.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit.

Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents example circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

FIG. **10** presents circuit **1000** as an example embodiment for the collection of energy from a dual polarity source. This may be used, for example, to collect atmospheric energy that reverses in polarity compared with the ground. Such polarity reversal has been discovered as occurring occasionally on Earth during, for example, thunderstorms and bad weather, but has also been observed during good weather. Such polarity reversal may occur on other planetary bodies, including Mars and Venus, as well. Energy polarity on other planets, in deep space, or on other heavenly bodies, may be predominantly negative or predominantly positive. Collector fibers (**130** from FIG. **2**) are capable of collecting positive energy and/or negative energy, and circuit **1000** is capable of processing positive and/or negative energy, providing an output which is always positive. Circuit **1000** may collect energy from one or more collection devices (**130** from FIG. **2**). Charging capacitor **1010** may be used to store a charge until the voltage at spark gap **1020** achieves the spark voltage. Capacitor **1010** is optional.

A plurality of diodes may be placed in a plurality of positions in circuit **1000**. The voltage from capacitor **1010** may be used to charge spark gap **1020** to a sufficient voltage. Spark gap **1020** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **1020** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **1020** arcs, energy will arc from an emitting end of spark gap **1020** to a receiving end of spark gap **1020**. The output of spark gap **1020** is electrically connected to the anode of diode **1022** and the cathode of diode **1024**. The cathode of diode **1022** is electrically connected to the cathode of diode **1026** and inductor **1030**. Inductor **1030** may be a fixed value inductor or a variable inductor. The anode of diode **1026** is electrically connected to ground. Capacitor **1028** is electrically connected between ground and the junction of the cathodes of diode **1022** and diode **1026**. Inductor **1035** is electrically connected between ground and the anode of diode **1024**. Inductor **1035** may be a fixed value inductor or a variable inductor. Capacitor **1070**, the anode of diode **1026**, inductor **1035**, and load **1050** are electrically connected to ground. Capacitor **1070** may be placed in parallel with load **150**.

FIGS. **11** and **12** provide example embodiments of vehicle **1110**, which utilizes electricity, the vehicle employing systems of energy collection provided herein. Vehicle **1100** in FIG. **11** is shown as an automobile vehicle, but could be any means of locomotion that utilizes electricity, including a car, a train, a motorcycle, a boat, an airplane, robotic rovers, space craft, etc. Vehicle **1100** in FIG. **12** is shown as a lunar rover vehicle. In FIGS. **11** and **12**, support rod **1110** is electrically connected to an electrical system in vehicle **1100**. Energy collectors **130** are electrically connected to support rod **1110** and may be used to supply energy to electrical circuits within the vehicle. A non-limiting use includes a top-off charge for a battery system, on-board hydrogen production, and/or assisting in the same. Energy collectors **130** may be used to augment the efficiency of the locomotion that utilizes electrical energy as well.

FIG. **13** provides an example embodiment of energy collection system **1200** in which diode **310** is used to isolate collection devices **130** from spark gap **1020** and load **150**. Collection devices **130** may comprise graphite, carbon fibers, carbon/carbon fibers, or a mixture thereof.

FIG. **14** provides an example embodiment of energy collection system **1300** in which a plurality of energy collection systems, such as that provided in FIG. **13**, are combined. Each leg consisting of collection devices **130** and diode **310** are connected in parallel with other legs, each leg electrically connected to trunk wire **1310**. The legs could also be connected serially. Trunk wire **1310** is electrically connected to a collection circuit, which may comprise load **150** and spark gap **1020** in any configuration that has been previously discussed. Each leg may comprise one or more collection devices **130** and at least one diode electrically connected between the collection devices and the collection circuit. Although three collection devices **130** are shown on each leg, any number of collection devices may be used. Although four legs are shown, any number of legs may be used.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A system of energy collection comprising: a plurality of support structure wires elevated above ground level; at least one collection device including at least one carbon or graphite fiber that collects electrical energy from the air and is electrically connected to the plurality of support structure wires; a load electrically connected to the plurality of support structure wires; and a dual polarity collection circuit electrically connected between the collection device and the load.

2. The system of claim **1**, wherein the collection device comprises a diode.

3. The system of claim **1**, wherein the collection device comprises:

a diode electrically connected between the load and the fiber.

4. The system of claim **2**, wherein the diode is elevated relative to the ground level.

5. The system of claim **1**, wherein the fiber comprises graphite, carbon fibers, carbon/carbon fibers, or a mixture thereof.

6. The system of claim **1**, further comprising a diode electrically connected between the at least one collection device and the plurality of support structure wires.

7. The system of claim **1**, wherein the dual polarity collection circuit comprises a plurality of diodes, at least one inductor, and at least one capacitor.

8. The system of claim **7**, wherein the capacitor is electrically connected in parallel with the load.

9. A vehicle employing a system of energy collection comprising: a means of locomotion; a support structure electrically connected to the vehicle; at least one collection device including at least one carbon or graphite fiber that collects electrical energy from the air and is electrically connected to the support structure; and a load electrically connected to the support structure.

10. The structure of claim **9**, wherein the collection device comprises a diode.

11. The structure of claim **9**, wherein the collection device comprises: a diode electrically connected between the load and the fiber.

12. The structure of claim **10**, wherein the diode is elevated relative to the vehicle.

13. The structure of claim **9**, wherein the fiber comprises graphite, carbon fibers, carbon/carbon fibers, or a mixture thereof.

14. The structure of claim **9**, further comprising a diode electrically connected between the at least one collection device and the support structure.

15. A system of collecting energy comprising:

a plurality of collection legs, each of the collection legs comprising:

at least one collection device including at least one carbon or graphite fiber that collects electrical energy from the air; and

a diode; and

a load electrically connected to ground.

16. The system of claim **15**, wherein the fiber comprises a surface having projections.

17. The system of claim **15**, further comprising a trunk line electrically connected between the plurality of collection legs and the load.

18. The system of claim **17**, further comprising a spark gap device electrically connected between the plurality of collection legs and the load.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support system. The support system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but graphene, carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

TECHNICAL FIELD

[0001] The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

[0002] The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

[0003] In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

[0004] Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

[0005] Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

[0006] While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

[0007] Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level; at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment electrically connected to the support structure; and a load electrically connected to the at least one collection device.

[0008] Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment from a support structure, the at least one collection device electrically connected to the support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level; and providing a load with an electrical connection to the at least one collection device to draw current.

[0009] Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

[0011] FIG. **1** is a circuit diagram of a weather energy circuit.

[0012] FIG. **2** is a perspective view of an example embodiment of many energy collectors elevated above ground by a structure.

[0013] FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

[0014] FIG. **2**B is a side view of an example embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

[0015] FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

[0016] FIG. **2**D is a side view of an example embodiment of a support structure for multiple energy collection fibers.

[0017] FIG. **2**E is a side view of a support structure for an energy collection fiber.

[0018] FIG. **2**F is a side view of an example embodiment of a support structure for an energy collection fiber.

[0019] FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

[0020] FIG. **3** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

[0021] FIG. **4** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

[0022] FIG. **5** is a circuit diagram of an example embodiment of an energy collection circuit for powering a generator and motor.

[0023] FIG. **6** is a circuit diagram of an example embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

[0024] FIG. **7** is a circuit diagram of an example embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

[0025] FIG. **8** is a circuit diagram of an example embodiment of a circuit for collecting energy.

[0026] FIG. **9** is a flow diagram of an example embodiment of collecting energy with a collection fiber.

[0027] FIG. **10** is a circuit diagram of an example embodiment of a circuit for collecting energy from a dual polarity source.

[0028] FIG. **11** is a system diagram of an example embodiment of an energy collection system connected to an automobile vehicle.

[0029] FIG. **12** is a system diagram of an example embodiment of an energy collection system connected to a lunar rover vehicle.

[0030] FIG. **13** is a system diagram of an example embodiment of an energy collection system comprising collection devices with a diode.

[0031] FIG. **14** is a system diagram of an example embodiment of an energy collection system comprising multiple legs of the system of FIG. **13**.

[0032] FIG. **15** is a system diagram of an example embodiment of a windmill with energy collectors.

DETAILED DESCRIPTION

[0033] Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An example embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An example embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

[0034] An example embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate collection ability.

[0035] In at least one example embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

[0036] A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An example embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

[0037] Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2**A-**2**G using a collection fiber embodiment. FIG. **2**A presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

[0038] Likewise, FIG. **2**B shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

[0039] FIG. 2C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

[0040] FIG. 2D presents another example embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0041] FIG. 2E provides another example embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

[0042] FIG. 2F presents another example embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

[0043] FIG. 2G provides two supports as provided in FIG. 2F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

[0044] FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** maybe connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

[0045] In an example embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

[0046] FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

[0047] FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes maybe placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

[0048] FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

[0049] FIG. **8** presents example circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820**

to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

[0050] FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

[0051] FIG. **10** presents circuit **1000** as an example embodiment for the collection of energy from a dual polarity source. This may be used, for example, to collect atmospheric energy that reverses in polarity compared with the ground. Such polarity reversal has been discovered as occurring occasionally on Earth during, for example, thunderstorms and bad weather, but has also been observed during good weather. Such polarity reversal may occur on other planetary bodies, including Mars and Venus, as well. Energy polarity on other planets, in deep space, or on other heavenly bodies, may be predominantly negative or predominantly positive. Collector fibers (**130** from FIG. **2**), which may comprise graphene, silicene, and/or other like materials, are capable of collecting positive energy and/or negative energy, and circuit **1000** is capable of processing positive and/or negative energy, providing an output which is always positive. Circuit **1000** may collect energy from one or more collection devices (**130** from FIG. **2**). Charging capacitor **1010** may be used to store a charge until the voltage at spark gap **1020** achieves the spark voltage. Capacitor **1010** is optional.

[0052] A plurality of diodes may be placed in a plurality of positions in circuit **1000**. The voltage from capacitor **1010** may be used to charge spark gap **1020** to a sufficient voltage. Spark gap **1020** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **1020** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **1020** arcs, energy will arc from an emitting end of spark gap **1020** to a receiving end of spark gap **1020**. The output of spark gap **1020** is electrically connected to the anode of diode **1022** and the cathode of diode **1024**. The cathode of diode **1022** is electrically connected to the cathode of diode **1026** and inductor **1030**. Inductor **1030** may be a fixed value inductor or a variable inductor. The anode of diode **1026** is electrically connected to ground. Capacitor **1028** is electrically connected between ground and the junction of the cathodes of diode **1022** and diode **1026**. Inductor **1035** is electrically connected between ground and the anode of diode **1024**. Inductor **1035** may be a fixed value inductor or a variable inductor. Capacitor **1070**, the anode of diode **1026**, inductor **1035**, and load **1050** are electrically connected to ground. Capacitor **1070** may be placed in parallel with load **150**.

[0053] FIGS. **11** and **12** provide example embodiments of vehicle **1110**, which utilizes electricity, the vehicle employing systems of energy collection provided herein. Vehicle **1100** in FIG. **11** is shown as an automobile vehicle, but could be any means of locomotion that utilizes electricity, including a car, a train, a motorcycle, a boat, an airplane, robotic rovers, space craft, etc. Vehicle **1200** in FIG. **12** is shown as a lunar rover vehicle. In FIGS. **11** and **12**, support rod **1110**, **1210** is electrically connected to an electrical system in vehicle **1100**, **1200**. Energy collectors **130**, which may comprise graphene, silicene, and/or other like materials, are electrically connected to support rod **1110**, **1210** and may be used to supply energy to electrical circuits within the vehicle. A non-limiting use includes a top-off charge for a battery system, on-board hydrogen production, and/or assisting in the same. Energy collectors **130** may be used to augment the efficiency of the locomotion that utilizes electrical energy as well.

[0054] FIG. **13** provides an example embodiment of energy collection system **1200** in which diode **310** is used to isolate collection devices **130** from spark gap **1020** and load **150**. Collection devices **130** may comprise graphite, carbon fibers, carbon/carbon fibers, graphene, silicene, and/or other like materials, or a mixture thereof.

[0055] FIG. **14** provides an example embodiment of energy collection system **1400** in which a plurality of energy collection systems, such as that provided in FIG. **13**, are combined. Each leg consisting of collection devices **130**, which may comprise graphene, silicene, and/or other like materials, and diode **310** are connected in parallel with other legs, each leg electrically connected to trunk wire **1410**. The legs could also be connected serially. Trunk wire **1410** is electrically connected to a collection circuit, which may comprise load **150** and spark gap **1020** in any configuration that has been previously discussed. Each leg may comprise one or more collection devices **130** and at least one diode electrically connected between the collection devices and the collection circuit. Although three collection devices **130** are shown on each leg, any number of collection devices may be used. Although four legs are shown, any number of legs may be used.

[0056] FIG. **15** presents a system diagram of an example embodiment of a windmill with energy collectors, which may comprise graphene, silicene, and/or other like materials in an example embodiment. A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1500** of suitable height and/or propeller **1520** of windmill tower **1500** may be equipped with energy collecting fibers **1530**, **1540**, which may comprise graphene, silicene, and/or other like materials in an example embodiment. Collecting fibers **1530**, **1540** may turn windmill **1500** into a power producing asset even when there is not enough wind to turn propellers **1520**. During periods when there is enough wind to turn propellers **1520**, collecting fibers **1530**, **1540** may supplement/boost the amount of energy the windmill produces.

[0057] A windmill is an engine powered by the energy of wind to produce alternative forms of energy. They may, for example, be implemented as small tower mounted wind engines used to pump water on farms. The modern wind power machines used for generating electricity are more properly called wind turbines. Common applications of windmills are grain milling, water pumping, threshing, and saw mills. Over the ages, windmills have evolved into more sophisticated and efficient wind-powered water pumps and electric power generators. In an example embodiment, as provided in FIG. **10**, windmill tower **1000** of suitable height and/or propeller **1020** of windmill tower **1000** may be equipped with energy collecting fibers **1030**, **1040**. Collecting fibers **1030**, **1040** may turn windmill **1000** into a power producing asset even when there is not enough wind to turn propellers **1020**. During periods when there is enough wind to turn propellers **1020**, collecting fibers **1030**, **1040** may supplement/boost the amount of energy the windmill produces.

[0058] Windmill **1500**, properly equipped with ion collectors **1530**, **1540**, such as a non-limiting example of fibers with graphene, silicene, and/or other like materials, can produce electricity: 1) by virtue of providing altitude to the fiber to harvest ions, and 2) while the propeller is turning, by virtue of wind blowing over the fiber producing electricity, among other reasons, via the triboelectric effect (however, it is also possible for the triboelectric effect to occur, producing electricity, in winds too weak to turn the propeller).

[0059] There are at least two ways that energy collectors may be employed on or in a windmill propeller to harvest energy. Propellers **1520** may be equipped with energy collectors **1530**, **1540** attached to, or supported by, propeller **1520** with wires (or metal embedded in, or on propeller **1520**) electrically connecting energy collectors **1530**, **1540**, which may comprise graphene, silicene, and/or other like materials, to a load or power conversion circuit. There may be a requirement to electrically isolate energy collectors **1530**, **1540**, which are added to propeller **1520**, from electrical ground, so that the energy collected does not short to ground through propeller **1520** itself or through support tower **1510**, but rather is conveyed to the load or power conversion circuit. Energy collectors may be connected to the end of propellers **1520** such as collectors **1530**. Alternatively, energy collectors may be connected to the sides of propellers **1520** such as collectors **1540**.

[0060] Alternatively, propeller **1520** may be constructed of carbon fiber or other suitable material, with wires (or the structural metal supporting propeller **1520** may be used) electrically connecting to a load or power conversion circuit. In the case of propeller **1520** itself being constructed of carbon fiber, for example, the fiber may be ‘rough finished’ in selected areas so that the fiber is “fuzzy.” For example, small portions of it may protrude into the air as a means of enhancing collection efficiency. The fuzzy parts of collectors **1530**, **1540** may do much of the collecting. There may be a requirement to electrically isolate carbon fiber propeller **1520** from electrical ground, so that the energy it collects does not short to ground through metal support tower **1510**, but rather is conveyed to the load or power conversion circuit. Diodes may be implemented within the circuit to prevent the backflow of energy, although diodes may not be necessary in some applications.

[0061] In an alternative embodiment, windmill **1500** may be used as a base on which to secure an even higher extension tower to support the energy collectors and/or horizontal supports extending out from tower **1510** to support the energy collectors. Electrical energy may be generated via ion collection due to altitude and also when a breeze or wind blows over the collectors supported by tower **1510**.

[0062] In alternative embodiments to windmill **1500**, other non-limiting example support structures include airplanes, drones, blimps, balloons, kites, satellites, cars, boats, trucks, (including automobile and other transportation conveyance tires), trains, motorcycles, bikes, skateboards, scooters, hovercraft (automobiles and conveyance of any kind), billboards, cell towers, radio towers, camera towers, flag poles, towers of any kind including telescopic, light poles, utility poles, water towers, buildings, sky scrapers, coliseums, roof tops, solar panel and all fixed or mobile structures exceeding 1 inch in height above ground or sea level.

[0063] An example embodiment of a support structure may also include cell phones and other electronic devices and their cases, including cases containing rechargeable batteries. For example, someone may set her cell phone or other electronic device or battery pack on the window ledge of a tall apartment building to help charge it. Other example support structures may include space stations, moon and Mars structures, rockets, planetary rovers and drones including robots and artificial intelligence entities.

[0064] Under some conditions, ambient voltage may be found to be 180-400 volts at around 6 ft, with low current. With the new generation of low current devices being developed, a hat containing ion harvesting material may provide enough charge, or supplemental charge, collected over time to help power low current devices such as future cell phones, tracking devices, GPS, audio devices, smart glasses, etc. Clothes may also be included as examples of support structures. Friction of the ion collection material (such as non-limiting examples of carbon, graphite, silicene and graphene) against unlike materials, such as wool, polyester, cotton, etc (used in clothes) may cause a voltage to be generated when rubbed together. Additionally, wind passing over the ion collection material has been demonstrated to generate voltage, even at low altitude. In an additional example embodiment, embedding collection devices into automobile tires (for example, in a particular pattern) could generate collectible voltage.

[0065] Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

[0066] It should be emphasized that the above-described embodiments of the present disclosure, particularly, any “preferred” embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment from a support structure, the at least one collection device electrically connected to the support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding **1** inch in height above ground or sea level; and

providing a load with an electrical connection to the at least one collection device to draw current.

2. The method of claim **1**, wherein the collection device collects energy by triboelectric effect.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises at least one of carbon, graphite, silicene and graphene.

8. A system of energy collection comprising:

a support structure, the support structure comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment electrically connected to the support structure; and

a load electrically connected to the at least one collection device.

9. The system of claim **8**, wherein the collection device collects energy by triboelectric effect.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **11**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises at least one of carbon, graphite, silicene, or graphene.

14. The system of claim **8**, further comprising a diode electrically connected between the at least one collection device and the support structure.

15. The system of claim **8**, further comprising: a switch connected in series between the at least one collection device and the load; and a capacitor connected in parallel with the switch and the load.

16. The system of claim **15**, wherein the switch comprises an interrupter connected between the load and at least one collection device, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

17. The system of claim **8**, further comprising: a motor for providing power, the motor connected between the at least one collection device and the load; and a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending, the means for suspending comprising at least one of an airplane, drone, blimp, balloon, kite, satellite, train, motorcycle, bike, skateboard, scooter, hovercraft, electronic device, electronic device case, billboard, cell tower, radio tower, camera tower, flag pole, telescopic pole, light pole, utility pole, water tower, building, sky scraper, coliseum, roof top, solar panel and a fixed or mobile structure exceeding 1 inch in height above ground or sea level;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

***Abstract*—This paper includes design and implementation result of an adaptive beam forming antenna for upcoming 5G and Internet of Things (IoT). Switched parasitic array antennas are low cost, small sized and compact circular array antennas that steer beam in a desired direction by variation in switching pattern of parasitic elements. The proposed antenna design has an active center element, which is surrounded by several symmetrically placed parasitic elements. The designed antenna has a gain of 8 dB and is capable of 360 degrees beam steering in steps of 60 degrees each. Simulations are validated with results of the fabricated antenna. Antenna beam is steered by controlling parasitic elements. Future application of Electronically Steerable Parasitic Array Radiator (ESPAR) antennas and switched parasitic array antennas in next generation communication networks and methods for reducing size of the antenna are also highlighted.**

***Index Terms*—Internet of Things, 5G, circular array, reconfigurable, smart antenna, adaptive beamforming, Switched-Parasitic Array**

I. INTRODUCTION

Smart antennas are capable of adaptive beam forming in accordance with the environment. Over the last three decades wireless communication has made rapid progress due to better modulation schemes and better error correction schemes. Wireless communication systems are replacing the wired ones. Antenna is an integral part of wireless devices. To meet the ever-increasing demand of higher data rate, smart antennas capable of adaptive beam forming are introduced as a potential solution to increasing data rate and improving signal-to-noise ratio (SNR) in upcoming 5G and Internet of Things (IoT) [1]. By using smart antennas Equivalent Isotropically Radiated power (EIRP) can be increased. EIRP denotes product of the transmit power (P_t) and transmit antenna gain (G_t), i.e.

$$EIRP = P_t \times G_t \tag{1}$$

From (1), it is observed that by using a smart antenna G_t increases, which in turn leads to the increase in the EIRP. The beam of an antenna can be steered by means of mechanical movement of a directional antenna or by electronic beam steering. Electronic beam steering is resilient and provides more accurate approximation of the desired signal source. Moreover electronic beam steering antenna does not involve moving parts. Therefore, there is less wear and tear on the antenna as compared to mechanical beam steering. Generally electronic beam forming is achieved by using phase shifters coupled with an array of antenna elements. The phase of an individual phase shifter is varied such that there is net constructive interference in the intended direction of the antenna beam and destructive interference in all other directions [2]. Hence, electronic beam steering is preferred over mechanical beam steering.

Electronically Steerable Parasitic Array Radiator (ESPAR) antennas use mutual coupling between antenna elements to steer the beams instead of phase shifters. Design of parastic array radiator antennas is discussed in [3], [4] in which there is a center active element surrounded by a circular array of passive elements, where each passive element is loaded with a specific reactance. ESPAR antennas are smaller in size as compared to phase array antennas because elements have to be placed at a quarter of wavelength or less distance from each other for effective mutual coupling. Hence, ESPAR antennas are cost effective and space efficient. In such antennas we have only one active element, therefore, only one feed is required. Consequently, ESPAR antennas have lower losses (due to single feed) as compared to phase array antennas [3].

Previously designed antenna Electronically Steerable Parasitic Raidator(ESPAR) antennas have all cylindrical element, including the feed element [6], [7]. In this paper we have proposed design of seven element ESPAR antenna with conical center(active element)[1]. Length of conical element is optimized using optimetrics in HFSS. Our proposed antenna has higher bandwidth as compared to previously designed ESPAR antennas. [6], [7]. In multiple-input-multiple-output (MIMO)

systems there are multiple transmit and and receive antennas. Each receive antenna receives signal over different propagation channels yielding diversity gain. The MIMO technique can increase system throughput and reduce propagation losses. Similarly diversity gain can also be achieved by using smart antennas. In particular, we can transmit the same signal in multiple directions through directional beams, such that they experience different propagation channels [4]. Our proposed antenna is more suited for MIMO applications compared to previously designed model because of its higher gain and improved bandwidth efficiency.

This paper focuses on the design of a seven element switched parasitic array antenna. The antenna is first simulated and then it is fabricated. Simulation results are validated with the hardware results. Previously done work on ESPAR and switched array antennas involve cylindrical monopole elements mounted on a ground plain [8] due to cylindrical nature bandwidth of active monopole is confined, subsequently bandwidth of switched array and ESPAR antennas is limited. Instead on cylindrical monopole element we have used tapered conical monopole. Due to tapered design bandwidth is enhanced.

II. SWITCHED PARASITIC ARRAY ANTENNA CONCEPT

The conceptual overview of the switched parasitic array antenna is given in Fig. 1. We have first simulated the antenna with seven monopole elements. There is one element at center which is surrounded by a circular array. Feed is applied to the center element and it is termed as active element, whereas elements in the circular array are parasitic elements. Parasitic array antennas do not involve phase shifters, so that the manufacturing cost is less as compared to the phase array antennas. Each element is separated from other element by a quarter of wavelength, thus mutual coupling phenomena comes into account and there is a shift in phase of current in each element because of this mutual coupling phenomenon. Since switched parasitic array antennas offer adaptive beamforming solution with compact size and low cost, they are likely to be used in future communication devices to increase data-rates [6], [7]. Parasitic array antennas have vast potential for usage in laptops, cell phones, WLANs etc.

A. *Mutual Coupling*

Mutual Coupling is basically the interaction between antenna elements in an array. Since parasitic elements are placed closer to each other (at a distance of $\lambda/4$) there will be mutual coupling.This mutual coupling phenomenon is responsible for a shift in phase of current induced in each element [8].The current induced by one antenna element in another antenna element [9] is given by (3)

$$I_2 = \frac{Z_{21}}{Z_{22}} \times I_0 \tag{2}$$

$$Z_{21} = \left|\frac{V_2}{I_1}\right|_{I_2=0} \tag{3}$$

$$Z_{21} = \left|\frac{V_2}{I_2}\right|_{I_1=0} \tag{4}$$

Here Z_{22} is constant as it is open-circuit output impedance. Z_{21} is open-circuit transfer impedenace from port 2 to port 1 and it can be approximated by graph shown in Fig. 2. From equation (3), beam can be steered in the desired direction by varying the phase of current I_2 [10].

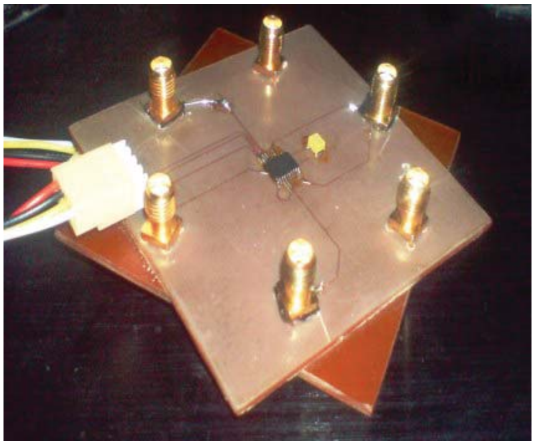

Fig. 3. RF PCB with Analog devices ADG 904 RF switches.

TABLE I
DESIGN PARAMETERS

Parameters	Values
Ground Skirt length	lambda/4
Monople Length	lambda/4
Frequency	2.45 GHz
Ground Radius	lambda/2
Monopole Radius	lambda/200
Ground Thickness	3 mm

B. *Beam Steering Mechanism*

In this work the designed antenna is capable of 360^0 beam steering in steps of 60^0. The beam steering is achieved by using two sets of 4:1 Analog devices multiplier switch ADG 904. Fig.3 shows RF PCB designed for beam steering. Beam is steered towards an element which is open. The open element behaves as a director and shorted elements act as reflectors. In order to achieve a maxima at 0^0, we make the element 1 open by using RF switch IC while other elements (i.e., elements 2,3,4,5 and 6) are shorted. This mechanism is similar to Yagi-Uda antenna where elements with shorter lengths in front of feed element act as directors and elements at rear of feed element acts as reflectors [11]. In Yagi-Uda antenna feed element is often a dipole or folded dipole.

III. PARASITIC ARRAY ANTENNA DESIGN

Design parameters and mechanical design of antenna is included in this section.

A. *Design Parameters*

Antenna design parameters are tabulated and the results are optimized using antenna simulation tools. Ground is skirted, since skirted ground provides mechanically sound model for PCB assembly to mount at back of antenna [12]. Skirt is $\lambda/4$ in length similarly each monopole element is lambda/4 in length and $\lambda/200$ is its radius.Table I shows the design parameters for the seven-element switched parasitic array antenna.

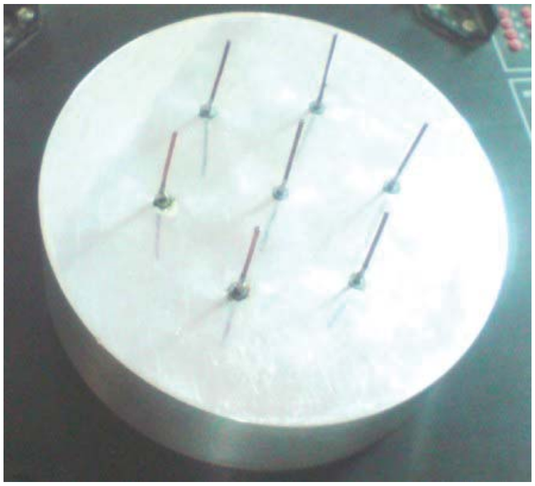

Fig. 4. Designed seven element parasitic switched array antenna.

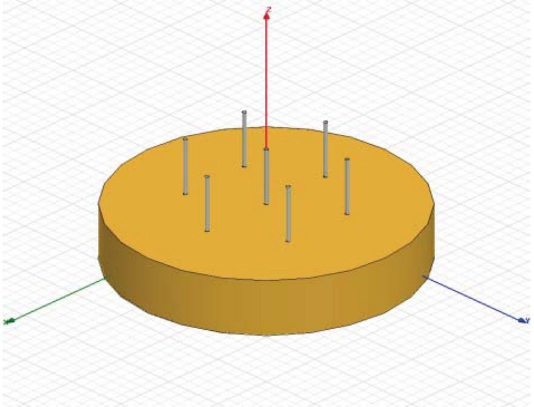

Fig. 5. Simulated antenna model.

B. *Mechanical Design*

Monopole elements are made by cutting copper wire of desired gauge i.e lambda/200 in radius [13] and these elements are soldered on pin of SMA connectors.Aluminum is used as ground plane. Electromagnetic waves are reflected by the ground. Instead of using seven dipole elements we have used seven monopole elements mounted on the ground plane [14]. Ground is made hollow in order to create space for mounting control circuitry [15]. Fig. 4 shows designed hardware.

IV. ANTENNA SIMULATION AND PLOTS

The antenna is first simulated and then simulated results are compared with the measured results of fabricated antenna. Simulated results were in line with the hardware results and 8 dB gain was observed in simulated results as well as in fabricated antenna. In simulation each of the parasitic element is loaded with lumped port excitation, simulating opening and shorting [16] of monopole elements. Fig. 5 shows simulated model.

TABLE II
MAXIMA PATTERN

Azimuth Angle	Element 1	Element 2	Element 3	Element 4	Element 5	Element 6
0 degree	Open	Short	Short	Short	Short	Short
30 degree	Open	Open	Short	Short	Short	Short

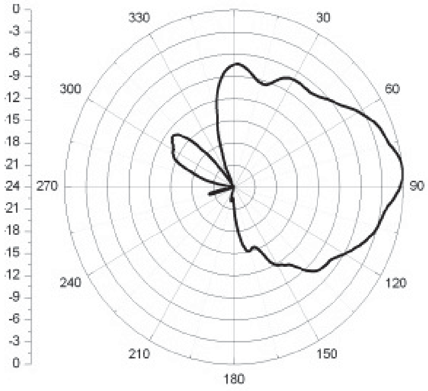

Fig. 6. Anechoic chamber results for $\theta=90^0$ (Beam in elevated because we are using monopole elements with finite ground).

Two dimension polar plots depicts the beam steering in the direction of given elevation angle, theta (θ) and azimuth angle, phi (ϕ). Anechoic chamber results for θ=90 and ϕ=0 and 30 degrees are shown in Fig. 7 and 8 respectively. Using large ground plane angle of elevation is reduced closer to 90^0. Fig. 6 shows anechoic chamber result for θ=90 one can observe small elevation form desired x-y axis because of ground skirt [17].In simulations elevation angle of 85^0 is observed. Fig. 6(a) shows antenna simulated plot for elevation angle θ and Fig. 6(b) shows anechoic chamber results.Anechoic chamber plot of Fig. 7 shows maxima at $\phi=0^0$, in order to get maxima at 0^0 elements from element number 2-6 are shorted and the element 1 is opened. Similarly Anechoic chamber plot of Fig. 8 shows maxima at $\phi=30^0$, in order to get maxima at 30^0 elements from element number 3-6 are shorted and element 1 and element 2 are open.

Traditional ESPAR antenna and switched parasiric array antenna have all cylindrical elements, including the active element [3], [4]. We have made center element conical instead of cylindrical. Due to conical nature of active element response our frequency range and improved. In order to validate the gain enhancement both models were simulated and results were compared. Fig 9. (a) shows conventional design and Fig. 9(b) shows simulated antenna with conical center element. Fig. 10 shows S_{11} plot for cylindrical active element. Considering -8_{dB} as cut off point bandwidth range from 2.358 GHz to 2.51 GHz (0.152 GHz). Fig. 11 shows $S-11$ plot for centre conical element, considering 8_{dB} as cut off point bandwidth ranges from 2.36 GHz to 2.555 GHz (0.195 GHz). Therefore my making center element conical we have improved bandwidth as compared to traditional switch array parasitic antennas. Low profile design for switched parasitic array antennas in also highlighted in [18].

V. FUTURE WORK AND CONCLUSION

5G networks will be designed for device to device, device to human and human to human interactions. High data rates are required to meet demands of 5G systems. One of proposed bands for 5G is in mm-Waves range i.e from 30GHz to 60GHz for such high frequencies path losses are considerable and beam steering antennas are way forward to overcome path

This is an author-produced, peer-reviewed version of this article. The final, definitive version of this document can be found online at *2016 Loughborough Antennas & Propagation Conference (LAPC)*, published by IEEE. Copyright restrictions may apply. doi: 10.1109/LAPC.2016.7807569

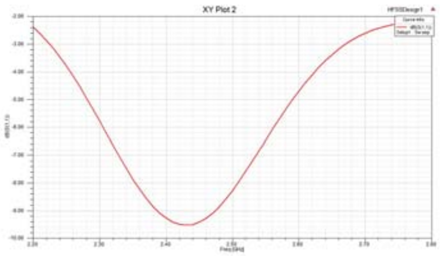

Fig. 10. S_{11} plot for conventional switched array antenna.

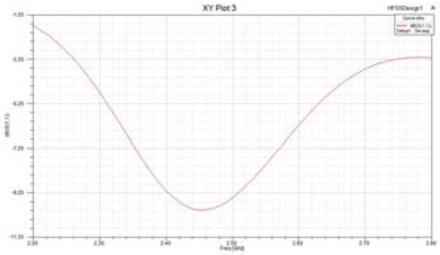

Fig. 11. S_{11} plot for center conical element switched array antenna.

losses [19]. ESPAR and switched parasitic array antennas provide a cost effective way of incorporating adaptive beamforming in future 5G and internet of Things (IoT) devices [20]. However for the efficient use of ESPAR antennas in mobile terminals the size of the antenna system must be reduced, for this further research on dielectric switched parasitic array antennas is underway. Seven element switched parasitic array antenna is designed that is capable of dynamic beam steering. Gain of 8dB is achieved practically. Simulated results are in line with the anechoic chamber results. Designed antenna increase the channel capacity by improving signal to noise ratio. Gain of 8dB was achieved in specified directions of elevation angle ,theta (θ) and azimuth angle, phi (ϕ). Antenna is optimized in terms of interference reduction for its use in wireless ad hoc networks, operating at frequency of 2.45 GHz. Bandwidth of designed antenna is 450 MHz and beam is steered in 360^0.

[57] **ABSTRACT**

The ambient broadband radio frequency field strength from broadcast stations is monitored (FIG. **4**) by periodic sampling (**50, 52**). A warning indication is provided if the field strength drops significantly. Drops in such field strength have been correlated empirically with the occurrence of seismic activity, usually several days later. Thus the indication serves as an early warning of an impending earthquake. In one preferred embodiment, a broadband, horizontal, very long monopole antenna (**40**) was connected to a rectifying and smoothing circuit (FIG. **3**) to provide a dc output proportional to the ambient rf field. This voltage is digitized (**50**), and using a suitably-programmed computer (**52**), the digital version of the field strength signal is sampled once per minute (**78**). A cumulative or running average of the minute samples is calculated (**80**) and held. Once per hour the latest running average is stored (**84**) and a standard deviation (SD) of the last 24 hourly stored running averages is calculated (**88**). If the SD exceeds a predetermined value, 0.3 in one embodiment, an alarm is triggered (**92**). The use of the SD eliminates the effect of day-to-day changes in the amounts of the variations of the ambient field strength, due to changes in tides and other factors. Once per day the samples are written (**96**) to a permanent storage file and a continuous plot of the field strength is also made (**14**). Preferably the alarm is triggered only if another detector also provides an indication (FIG. **6**), thereby to eliminate the effect of machine error.

FIG 6

SEISMIC WARNING SYSTEM USING RF ENERGY MONITOR

BACKGROUND—FIELD OF INVENTION

This invention relates to the prediction of the fugure occurrence of seismic activity, particularly to the advance notification of earthquakes through the monitoring of ambient radio frequency (rf) energy.

BACKGROUND—DESCRIPTION OF PRIOR ART

Heretofore, insofar as we are aware, seismology, the science of earthquakes, has not been able to make any near-term predictions of earthquakes.

While scientists have known that certain animals may have had some sort of advance knowledge of quakes, due to the fact that they exhibited peculiar behavior before quakes, and not at other times, this behavior has not been consistent and reliable enough to be of practical use.

Also, while scientists have also been able to predict thunderstorms in advance by monitoring the ambient electrostatic field (see, e.g., U.S. Pat. No. 3,611,365 to Husbyorg and Scuka, 1968; 3,790,884 to Kohl, 1974; and 4,095,221 to Slocum, 1978), they have not been aware of any corresponding system for earthquake prediction.

Scientists have been able actually to detect earthquakes during their occurrence by monitoring air pressure variations (e.g., as described in U.S. Pat. No. 4,126,203 to Miller, 1978) and by monitoring the earth's physical movement by seismographs but, again, science has not been aware of any system for short-term advance detection or prediction of quakes.

Due to the devastating effects of quakes to property, life, and limb, public and governmental authorities would derive great benefit from any system which could provide short-time advance notification of great earthquakes. As it is now, except for aftershocks, which seismologists know will occur after any large quake, all great and small quakes occur without warning. Because people in the vicinity of such quakes are unprepared, they often are in places of great vulnerability, such as beside or inside collapsible buildings, so that severe and human injury usually occurs during a quake. Also, property itself is left vulnerable, e.g., by leaving automobiles in or near collapsible buildings, leaving gas and electricity connected such that disruption of these facilities causes fires, and leaving other valuable property in vulnerable areas. If advance notification of a large quake could be provided to the public and civil authorities, people and valuable property could be evacuated and protected, thereby preventing deaths, injuries, and greatly reducing property damage. Further, advance notification of quakes would eliminate the severe psychological trauma which often affects large segments of the populace due to the surprise occurrence of quakes.

OBJECTS AND ADVANTAGES

Accordingly several objects and advantages of the invention are to provide a reliable and effective method of earthquake prediction, to provide a method of preventing death, injuries, and reducing property damage in earthquakes, and to provide a method of reducing the psychological trauma which often accompanies quakes due to their surprise occurrence. Additional objects are to provide such a system which is easy to use, economical, reliable, and portable. Further objects will become apparent from a consideration of the ensuing description, taken in conjunction with the accompanying drawings.

BACKGROUND—THEORY OF INVENTION

The following is a discussion of the background theory of the invention. While we believe it to be technically accurate, we do not wish to be limited by this theory since the operability of the invention has been empirically verified, as will be apparent from the later discussion.

We have recently worked work with the reception and utilization of broadband radio-frequency reception, e.g., for low-power utilization applications, as discussed in the copending application Ser. No. 06/539,223 of Joseph B. Tate, filed Oct. 6, 1983. While doing this work, we have noted that the antenna's output voltage fluctuated with time due to certain, known causes.

First, we noted that the higher we placed an antenna above the ground, the the greater the output signal it provided. We have observed this by raising the physical height of an antenna and observing an increase in power output, and also by observing variations in the output of a fixed antenna near a body of ocean water as a function of the tides: the antenna's output was greatest at low tide and lowest at high tide. We believe that the the change in water level, which serves as a ground plane, effectively lowers or raises the height of the antenna above the ground.

We also noted that the antenna's output was affected by solar flares to a limited extent; these caused the antenna to produce a higher output voltage during their occurrence. We believe this phenomena is caused by an increase in the level of ambient ionization due to the flares.

Further, we noted that the antenna's output dropped at certain irregular times; at first we would not attribute any cause to these drops. However investigation enabled us to correlate these drops with the subsequent occurrence of seismic activity. We found that the magnitude of the drop was proportional to the size of the subsequent earthquake.

Certain phenomena have been discovered to precede earthquakes. These include an anomalous uplift of the ground, changes in the electrical conductivity of rock, changes in the isotopic composition of deep well water, changes in the nature of small earthquake activity (e.g., bunching of small foreshocks), anomalous ground tilt or strain changes, changes in physical properties, such as porosity, electrical conductivity, and elastic velocity in the hypocentral region. Earthquake, McGraw-Hill Encyclopedia of Science And Technology, 1960; Earth by F. Press, W. H. Freeman & Co., 1974.

Phenomena associated with rocks have attracted much recent attention. Wm. Brace of the Mass. Inst. of Technology has found that when rocks were squeezed or compressed, just before they fractured, they tended to develop hairline cracks, swell or dilate (dilatancy), become more porous and electrically conductive, and transmitted high frequency seismic-like waves more slowly. Two of Brace's former students, Amos Nur of Stanford University and Christopher Scholz of Lamont-Doherty furthered Brace's work, connecting the dilatancy theory with seismic P-wave velocity shifts and rock resistivity changes as a precursor for earthquakes. See. e.g., Brace, Orange, and Madden, J. Geophys Res., 70(22), 5669, 1965; A. Nur, Bull. Seis. Soc. of Amer., V 62, Nr. 5, pp. 1217–1222, 1972 Oct.; Earthquake by B. Walker, Time-Life Books, 1982.

Based upon the above background, we have developed a theory as to the cause of this drop in antenna output as a precursor or predictor of earthquakes. We believe that before a quake occurrs, the pressure within underground rock bodies temporarily increases greatly, causing the rocks to dilate and become conductive, in accordance with the works of Brace, Nur, and Scholz. This increase in conductivity effectively raises the ground plane, thereby causing the antenna's output to decrease temporarily.

Thus before the occurrence of a quake, the underground pressure increases greatly temporarily, causing underground rock bodies to swell and become more conductive, thereby raising the ground plane, which in turn causes the voltaic output of nearby antennas to drop.

We accordingly constructed an apparatus to automatically monitor antenna output and provide a suitable indication if the output level dropped significantly. The indication was calibrated empirically after much experimentation so as to filter ouo the effects of solar- and tide-caused variations. We did this by arranging the apparatus so that an output indication was provided only if the antenna output dropped a predetermined degree beyond its average level; we utilized statistical filtering techniques to accomplish this.

DRAWINGS

FIG. 1 shows the front panel of a Seismic Early Warning (SEW) apparatus according to the invention.

FIG. 2 is a plot of voltage (representing ambient rf level) v. time as measured by the apparatus of FIG. 1.

FIG. 3 is a schematic diagram of an ambient power module circuit (used in the SEW apparatus) for producing a DC output voltage proportional to the ambient rf energy

FIG. 4 is a block diagram of a computer in the apparatus of FIG. 1.

FIG. 5 is a flowchart which depicts the operation of the the SEW system.

FIG. 6 is a flowchart which depicts the operation of an optional alarm trigger system useable with the SEW apparatus.

FIG. 1—SEISMIC EARLY WARNING APPARATUS

In accordance with the invention, a seismic early warning apparatus is provided as shown in FIG. 1. The apparatus consists of a housing containing a general purpose computer (not shown), a disc drive **10**, an analog system comprising a microampere meter **12** arranged to monitor direct current (which is proportional to the ambient rf energy), and a direct current strip chart recorder **14** arranged to provide a continuous indication of the current antenna output, which will be called the ambient power level. A hexidecimal keypad **16** is provided to enter data, such as time, for entering programs and changes and for operating the system according to preset codes. The time, date, and voltaic level of the antenna's output are continuously indicated by digital readouts **18**, **20**, and **22**, respectively. A screen display **24** is provided to display graphic and alphanumeric information of the current status of the apparatus and previous data records.

Lastly the apparatus includes four status indicating lamps, which preferably are LEDs (light-emitting diodes) as follows: A green LED **26** indicates that the system is on and functioning normally. A yellow LED **28** indicates that the system has detected an event, namely the occurrence of a drop in ambient power below the preset level, which would be the prediction of an impending earthquake. A red LED **30** is provided as backup confirmation of the occurrence of the event; LED **30** is illuminated when a duplicate receiving system also detects an event. A blue LED **32** indicates initiation of operation of an automatic telephone dialer within the system, which has been preprogrammed to dial a predetermined number and provide a warning in the event of an occurrence of an alarm condition. Lastly the apparatus includes a hard copy output port **33** for providing printed graphic and numeric outputs of all system data.

FIG. 2—AMBIENT RF LEVEL V. TIME BEFORE QUAKE

FIG. **2** illustrates a reproduction of an actual plot of a voltage as a function of time, which voltage was proportional to the ambient RF (radio frequency) level, from the period from before to after a relatively large earthquake. This plot, which is typical of many we have observed before a quake, was made by deriving the voltage with a 30-meter, long-wire monopole antenna (not shown) which was mounted horizontally and which extended over San Francisco (Richardson) Bay easterly from Sausalito, California, 9 meters above sea level. The antenna thus intercepted and converted to an RF voltage the ambient RF energy, mainly from local (San Francisco area) AM radio stations. We rectified and filtered the output of the antenna using one-half of the circuit of FIG. **3** (described below) to provide a DC voltage which was plotted on a conventional ink-on-paper plotter. Note that on the section of the chart for Apr. 19 (1984), which begins at time 0:00 (midnight) and ends at 24:00, the voltage or ambient RF power level at the antenna increased and fell and then increased slightly in the 24-hour period. This wavelike variation typically occurs on a daily basis and is caused by tides: the peaks occurring at low tide when the effective ground plane provided by the water drops and the troughs occurring at high tide when the ground plane rises.

On Apr. 20, from about 8:00 to about 12:00, a sharp and constant-level dip in the ambient rf power occurred, as indicated. The magnitude of this pronounced dip is far greater than the normal tide-caused variations, as is its beginning and ending slope.

Thereafter, from Apr. 20 to Apr. 23, the plot (not shown) continued unremarkably, albeit with a slight variation from normal.

The same occurred on Apr. 24, with the plot actually being generally similar to a normal day. However at 13:15 on Apr. 24, as indicated, a large, Richter magnitude 6.0 quake occured near Hollister, Calif., about 340 km away from the antenna. No change in the plot occurred at this time.

Correlation of this quake with the plot's marked dip of Apr. 20 was made by the repeated observation of dozens of similar dips and subsequent quakes. Pronounced dips were always followed by a quake several days later. Thus we have empirically established causal and theoretical connections between pronounced dips of the type shown and the occurrence of subsequent seismic activity.

FIG. 3—AMBIENT POWER MODULE

The circuit of FIG. **3** is used to convert the ambient RF energy to a direct voltage which can be used and handled by data processing equipment. Designated an ambient power module (APM), it is connected to an antenna **40**, preferably a broadband monopole antenna of the type described in the preceeding section. The distal end of the antenna is free and its proximal end is connected to the circuit via two capacitors **Cp1** and **Cn1**, each being in series with the signal line for coupling and each having a value of 0.047 microfarad. Taking the left or negative side of the circuit first, it comprises two rectifiers (diodes) Dn1 and Dn2 (1N34 type) and a filter capacitor Cn2 (40 microfarads). Rectifier Dn1 is connected in parallel to the signal path and rectifier Dn2 is connected in series, in the wellknown voltage multiplier arrangement. Capacitor Cn2 is connected in parallel across the output of the APM to smooth the rectified output. The right or positive side of the circuit is similar, except for the polarity of the diodes.

In operation, an RF voltage is developed across antenna **40**; this voltage is voltage multiplied by the two rectifiers on each side of the circuit. The resultant direct voltages are smoothed or filtered by capacitors Cn1 and Cp2 and are supplied to output terminals **42** and **44**. A positive version of this direct voltage is plotted in FIG. **2**, as described above.

FIG. 4—BLOCK DIAGRAM OF COMPUTER

A computer for performing the monitoring and alarm functions of the invention and which is provided within the apparatus of FIG. **1** is shown in FIG. **4**. The computer receives the positive voltage from the APM (FIG. **3**) and processes this, providing an alarm if the voltage dips a predetermined amount from its recent average value.

The computer comprises an analog to digital converter (ADC) **50** which is arranged to convert the positive DC voltage from the AAPM to digital form, preferably in the form of a parallel signal at the output of ADC **50**. The digitized voltage from ADC **50** is supplied to a central processing unit **52**, which is a type 68000 microprocessor or computer on a chip. CPU **52** and ADC **50** are clocked by a clock **54** in conventional fashion.

CPU **52** operates on instructions from a program contained in an electricallyprogrammed read only memory (EPROM), the program being listed later. CPU **52** temporarily stores data in a read and write memory (RAM) **58**. CPU **52** also supplies output data to display screen **24**, disc drive **10**, and hard-copy printer **26'**, each of which was already described in conjunction with FIG. **1**.

CPU **52** can receive input data manually from hexidecimal keypad **16** (see FIG. **1**) via a keyboard encoder **60**.

CPU **52** can supply an alarm output to a radio transmitter or automatic telephone dialer **62** via a modem (modulator-demodulator) **64** for connecting the CPU to a phone (not shown).

As also indicated in FIG. **4**, the negative output of the AAPM of FIG. **3** is connected to ammeter **12** and chart recorder **14**.

FIG. 5—FLOWCHART OF SEISMIC EARLY WARNING SYSTEM

In operation, the system of FIG. **4** operates under control of the program in EPROM **56** in accordance with the flowchart of FIG. **5** as follows:

Startup: Blocks **70** and **72**: An initialization and startup sequence is first initiated when the machine is turned on, as indicated by block **70**; this sets all registers and counters to zero. The time and data are then set manually (using EPROM **56**), as indicated by block **72**.

Clock Reading: Blocks **74** and **76**: Next, under automatic program control, the machine reads the elapsed time on its clock display register, as indicated by block **74**. If the "seconds" register does not indicate the number one (#1), the machine continues to read the clock, as indicated by the "no" output of decision block **76**.

Minute Sample: Block **78**: When second #1 appears, as it will once per minute, the decision in block **76** will be "yes", so that the machine will take one sample of the rectified, smoothed, and digitized version of the antenna's output, i.e., the output of ADC **50** of FIG. **4**, as indicated in block **78**. This sample will be taken once per minute, i.e., whenever second #1 is displayed.

Running Average: Block **80**: Next, as indicated by block **80**, a running average of the samples taken in block **78** is calculated. This is done by accumulating the samples to keep a running total of their values, counting the number of samples accumulated, and dividing the running total by the latest number of samples each time a new sample is taken.

Store Hourly Average: Blocks **82** and **84**: Next, as indicated in block **82**, a test is made to see if the time display register indicates that minute number one (#1) has come up. If not, the decision is "no" and the clock is read again (block **74**). If the decision is "yes", as it will be once per hour, the running average in the accumulator will be stored (block **84**) and the accumulator will be cleared or reset to zero.

One Day Test: Block **86** ("No" decision) and Block **94**: Next the machine makes a test to see if 24 hours have passed. If not, the machine will not be able to make any valid statistical determinations. Thus it must run at least 24 hours before being operative. Assuming the decision in block **86** is negative (24 hours have not yet elapsed) another test is made (block **94**) to see if hour zero is indicated, which will occur once per day. If hour zero is not indicated, (decision in block **94** is negative), the clock will be read again (block **74**) in the usual loop.

Calculate SD: Block **86** ("Yes") and Block **88**: If a full day has elapsed, so that valid statistics can be calculated ("yes" from block **86**), the standard deviation (SD) of the last **24** hourly averages is calculated, as indicated in block **88**. This is done once per hour. The calculation is made using the usual SD formula

$$SDDEV = SQR([sum(x-X)^2]/n)$$

where SDDEV=SD; SQR=the square root; sum=the sum of; x=the individual hourly averages; X=the mean of the hourly averages; and n=the number of individual hourly averages. Essentially the SD is calculated by taking the mean of all of the hourly averages, taking the difference or deviation of each hourly average from the mean, squaring each deviation, taking the mean of the squared deviations, and then taking the square root of the mean of the squared deviations.

Evaluate SD: Block **90**: The SD is then evaluated to see if it is greater than 0.3. This value has been empirically determined to be the level at which a the present apparatus will provide a reasonably positive indication that an earthquake will occur, while neglecting the effects of non-seismic-caused variations. If the SD is less than 0.3, (a "no" output from block **90**), this indicates that the last hourly average was not greatly different from the average of the last 24 hourly samples, so that no alarm need be indicated. I.e., the antenna's output did not drop significantly to indicate an impending earthquake. Thereupon the program moves to block **94**, where a test is made for the existence of hour zero, as described. If, however the SD exceds 0.3 ("yes" output of block **90**), this indicates that the antenna's output has dropped significantly so as to affect the last hourly average, thereby to indicate an impending earthquake.

Alarm: Block **92**: In response to the Yes output of block **92**, an alarm is triggered (block **94**). The alarm may be a bell, the dialing of a telephone to a location where personnel are present if the apparatus is placed at a remote or non-manned location, or the initiation of the further program of the Flowchart of FIG. **6**, the alarm trigger sequence. To eliminate the possibility of equipment failure and to provide confirmation from another apparatus at another location, we prefer to provide an alarm only upon confirmation from another apparatus, as discussed in the description of FIG. **6** below.

Make Record: Block **94** ("Yes") and Block **96**: If hour zero is being displayed when the operation of block **94** is performed, which occurs once per day at midnight, the operation of block **96** will be performed, i.e., the data in the registers will be stored to disc to create a permanent record and the registers will be cleared to create new data for the next day. However the previous 24 hourly averages are still stored at all times so that a valid SD can be calculated and tested every hour. After the operation of block **96**, the clock is read again in accordance with the regular program (block **74**).

FIG. 6—ALARM TRIGGER FLOWCHART

The sequence of FIG. **6** is performed when the alarm is triggered in block **92** of FIG. **5** as an optional, but preferred backup confirmation of an impending earthquake. The operations in the backup confirmation system will be described briefly.

Beginning with blocks **100** and **102**, the system is continually tested (hourly) for the occurrence of a SD of the hourly averages of greater than 0.3. If the SD is greater than 0.3, the alert indicator (**28** of FIG. **1**) is triggered (block **104**) and the program initiates a test (block **106**) to see if a backup apparatus (not shown) is present. If so (yes output of block **106**) the backup apparatus is also checked (blocks **108** and **110**). If the backup does not indicate an excess SD, the indicators are reset to normal (block **112**), but if backup confirmation is received, the alarm indicator (**30** of FIG. **1**) is triggered per block **114** and a preprogrammed telephone number is dialed and indicator **32** is lit (block **116**).

After the alarm condition is manually checked and the system is reset, the output of block **120** will be a "yes" and the system will be reset to normal (block **112**). If a valid alarm condition is indicated and confirmed, civil authorities will have time (usually several days) to notify the populace, evacuate the area, or take any other needed precautions, depending on the size of the impending quake as indicated by the size of the standard deviation.

PROGRAMS:

The attached computer programs will perform the calculations and operations above described. These programs are written in the BASIC programming language. Program "RECVOLT.AL" runs continuously and writes the information to disc every 24 hours. Program "GRASTAT.*" is manually run; it reads data from the disc and plots it on the screen or printer, as desired.

While the above description contains many specifications, these should not be construed as limitations on the scope of the invention, but merely as an exemplification of one preferred embodiment thereof. Many other variations are possible. For example, the programming language can be changed, or the calculations and operations can be performed with hard-wired conventional circuitry in lieu of a programmed computer. More than two corroboration receivers can be used, and these can be placed at various locations. In lieu of testing the antenna's output reception of the area's AM stations, a special, decicated transmitter with a special, dedicated frequency and a specially-tuned matching receiver can be used to avoid depedence on stations which are not under the control of the earthquake prediction system and its personnel. The transmitter and the receiver should be spaced apart geographically, preferably by at least several km, so that the ground plane conduction phenemon can operate. Also the transmitted signal can be a specially-coded or modulated signal, or it can be an auxiliary signal of a regular transmitter, e.g., a SSB or SCA signal, together with a matching receiver. In lieu of a test for an excess SD, the apparatus can be arranged to test for a predetermined drop in the value of the antenna output from its immediately previous value or its average value over a predetermined period, such as an hour or day, or for a drop having greater than a predetermined slope. Accordingly the full scope of the invention should be determined by the appended claims and their legal equivalents, and not by the examples given.

"RECVOLT.AL"

We claim:

1. A method for providing an early warning of the future occurrence of an earthquake, comprising the following steps:

(a) measuring the field strength of at least one broadcast radio frequency signal at a location separated from the place of transmission of said signal, and

(b) providing a humanly-sensible indication if the strength of said signal decreases beyond a predetermined amount from a previous value thereof.

2. The method of claim 1 wherein said measuring is done on a broadband basis so as to measure the strength of a plurality of radio signals.

3. The method of claim 1 wherein said measuring is performed by rectifying and filtering said radio frequency to provide a direct current voltage and wherein said indication is provided in response to a predetermined drop in the value of said voltage.

4. The method of claim 1 wherein said indication is provided if the strength of said signal decreases a predetermined amount from an average value thereof.

5. The method of claim 4 wherein the value of said signal is periodically sampled for a predetermined period, a standard deviation of the resultant samples is calculated, and said indication is provided if said standard deviation exceeds a predetermined value.

6. The method of claim 4 wherein said signal is sampled once per minute, the resultant minute samples are averaged each hour, and the resultant hourly averages are tested to determine if the latest hourly average has

deviated from previous hourly averages beyond a predetermined amount.

7. The method of claim 1 wherein said indication is provided only if at least wo separated receivers detect said predetermined drop in the strength of said signal.

8. The method of claim 1 wherein a visible record of said signal's field strength is plotted as it is measured.

9. The method of claim 1 wherein the strength of a plurality of broadcast signals are measured by rectifying and filtering said signals to provide a direct current voltage, said direct current voltage is periodically sampled, the resultant samples are averaged periodically to provide periodic averages, the standard deviation of said periodic averages is calculated, and said indication is provided if the value of said standard deviation exceeds a predetermined value.

10. A system for providing an early warning of the future occurrence of an earthquake, comprising:

(a) means for measuring the field strength of a least one broadcast radiofrequency signal, said means being arranged to measure said field strength at a location separated from the place of transmission of said signal, and

(b) means responsive to the measured strength of said signal for providing a humanly-sensible indication if said measured field strength decreases beyond a predetermined amount from an average value thereof.

11. The system of claim 10 wherein said means for measuring comprises a broadband receiver for measuring the strength of a plurality of radio signals.

12. The system of claim 10 wherein said means for measuring comprises means for rectifying and filtering said radio frequency signal to provide a direct current voltage and wherein means for providing said indication is arranged to do so in response to a predetermined drop in the value of said voltage.

13. The system of claim 11 wherein said means for providing said indication is arranged to do so if the strength of said signal decreases a predetermined amount from an average value thereof.

14. The system of claim 13 wherein said means for measuring comprises means for periodically sampling the value of said radio signal for a predetermined period, and wherein said means for providing said indication is arranged to calculate the standard deviation of the resultant samples and to provide said indication if said standard deviation exceeds a predetermined value.

15. The system of claim 13 wherein said means for periodically sampling said signal is arranged to take a sample once per minute and to average the resultant minute samples each hour, and wherein said means for providing said indication is arranged to do so by testing the resultant hourly averages to determine if the latest hourly average has deviated from previous hourly averages beyond a predetermined amount.

16. The system of claim 10 wherein said means for providing said indication is arranged to do so only in response to the detection of a predetermined drop in the strength of said signal by two separated receivers.

17. The system of claim 10 further including means for making a visible record of said signal's field strength as it is measured.

18. The system of claim 10 wherein said means for measuring includes means for measuring the strength of a plurality of broadcast signals by rectifying and filtering said signals to provide a direct current voltage, means for periodically sampling said direct current voltage, means for averaging the resultant samples periodically to provide periodic averages, and wherein said means for providing said indication includes means for calculating the standard deviation of said periodic averages, and providing said indication if the value of said standard deviation exceeds a predetermined value.

19. The system of claim 10 wherein said means for measuring and providing said indication comprises a broadband receiver arranged to provide a direct current output voltage, an analog to digital converter, and a programmed computer arranged to receive the outpt of said converter.

20. The system of claim 19 further including means for periodically storing received field strength values and providing a visible plot of the continuous value of said field strength.

UNITED STATES PATENT AND TRADEMARK OFFICE

CERTIFICATE OF CORRECTION

PATENT NO. : 4,628,299
DATED : 1986 Dec 9
INVENTOR(S) : J. B. Tate and D. E. Brown

It is certified that error appears in the above-identified patent and that said Letters Patent are hereby corrected as shown below:

Col. 1, line 6, change "fugure" to --future--.
Col. 3, line 24, change "ouo" to --out--.
Col. 8, line 25, change "specifications" to --"specificities--.
Col 8, near bottom, delete handwriting at top of program listing reading "8299 Issue of 12-9".

John Bedini's "Scalar Beam" device

Here's a suggestion for "scalar" experiments from a conversation with John Bedini. Mr. Bedini encourages everyone to try this experiment, but warns us that this device is patent applied for, so you should only build a single unit for your own use.

The brush noise from the DC motor provides a pulse signal to the coil, which modulates the 'colliding' field pattern of the magnets and creates interesting scalar effects within a narrow pencil-beam pattern which extends from each face of the magnet out to a few inches.

Mr. Bedini suggests these experiments:

Purchase two identical music CDs. Listen to both to verify that they are identical. Now let the "scalar beam" play all over the surface of one of the CDs for about one minute. You may want to build a simple rotating platform to make this process more convenient. Now play the two CDs and compare them again. Hear any difference? (Note, this process is patent pending, so do not use it for any other purpose except to demonstrate the reality of the effect)

Connect a small probe-coil to an oscilloscope, then move it around in the beam and observe the waveforms.

Taste some wine, then put it in a small airtight container and place it against the magnet face for a few (minutes? hours?) Taste it again. Improvements? Try it with and without the power supply connected to verify that any changes are caused by the scalar beam and by just the magnetic field.

FROM : Some tests I intend to try (but as yet have not!):

Place various foodstuffs in the beam then compare flavor with untreated samples.

Grow two collections of plants, water one with normal water, water the other with water that's been treated by several minutes??hours?? exposure to the beam. As a control, use water which was held nearby identical magnets but without the coil.

Aim the beam directly at a plant for many days, compare it with another untreated plant as a control. (Shield the magnet, or place a similar magnet-block near the control plant.)

Sprout two groups of seeds, one treated and one untreated, and look for differences in number, health, growth rate, etc., between the two groups.

Measure the growth of the tip of a plant stem by using a tiny lever, mirror, and laser beam. Graph the growth rate, then treat the plant with the scalar beam and look for changes in the growth rate. (Note that this method can also be used to observe plants' realtime response to numerous stimuli both conventional and "weird." Fertilizer? Light? Music? Magnetism? Pyramids? Good/Bad thoughts?)

Observe microscopic lifeforms in pond water, then expose them to the beam and see if their behavior changes while it is operating. Or, expose the water to the beam for several minutes??hours??, then compare the number and activity of lifeforms in the water with an untreated bottle. Or, compare the effects of adding treated or untreated water to the slide under the microscope.

Use an opamp buffer and an audio amplifier to listen to the noise output of a capacitor which is shielded in a thick copper box, (or does a resistor or transistor work better?) then aim the beam at the box and listen for signals, or monitor changes to component values. See: http://amasci.com/freenrg/grav3.txt, Hodowanec's capacitor-based gravity detector, for more info.

Apparatus and method for reducing electronic relaxation noise present information recording medium

US5487057

A method and apparatus is provided for reducing relaxation noise in a conducting medium. The device is fabricated by affixing two magnets at like, repelling poles; wrapping said magnets with a coil of wire in an orientation orthogonal to the interface between the joined magnets and the like poles of the magnets to form a magnetic unit; connecting said coil to a motor means, an electrical power supply means and a switch means; attaching a spindle to said motor means. The spindle receives said conducting medium. The apparatus can be in a housing. The conducting medium is placed on said spindle. By activating the device, a modulated magnetic electromagnetic field is created simultaneous to the spinning of the conducting medium. The information recording medium rotates through the modulated electromagnetic field, thereby reducing the relaxation noise.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The invention relates to the general field of playback of recorded conducting media or conductors, more specifically, an apparatus and method that reduces electronic relaxation noise, also known as "linger noise", that exists in information recording medium.

2. Description of Related Art and Information

The utility of the present invention is based on fundamental laws of nuclear and electronic physics at the electron level, particularly with respect to electron gas relaxation phenomena in conductors immediately preceding the initiation of normal current flow per ohms law.

For current to flow through a medium conductor or a conducting plate (conductor) that involves electromagnetic (EM) effects in recording and playback, and in transmission of signals, and thus to provide signals through normal circuitry, conducting plates, etc., a finite time is required before the flow is established, and before stability, referred to as a "stable signal" or stable flow pattern, can be established. This time delay is referred to as electron gas relaxation time.

The relaxation phenomenon involves at least three major stages, all of which must be substantially completed before the relaxation time is actually complete, and coherent signals or patterns are being transmitted in the conductor. Further, the relaxation time involves damped oscillations.

The first stage in the relaxation time is the relaxation of the electrical charge density. Electrons initially distributed throughout the conductor are "excited" by taking on excess energy in the form of potential gradients across them. They are now substantially involved in working their way to the surface, since most of the current flow must occur on the surface of the conductor, not in its interior. If the total charge is not zero, a very highly non-linear first phase results, and the division between first and second stages is substantially blurred.

A simplifying assumption is made, that the initial charge is zero, so that the compensated charge fluctuations may be described by linear equations. Then the relaxation of electrical charge density can be assumed to be mostly independent of the initial conditions and of the size and shape of the conductor.

Treating the Drude electron gas model as applicable, and assuming each electron is independent of the rest, damped harmonic oscillator equations result for the relaxation. This yields a short relaxation time for stage 1. This erroneously short relaxation time basically results from assuming that the electrons move rather independently and are de-coupled. With coupling remaining as is almost always the case, a combination of stage 1 and stage 2 actually applies immediately, and sometimes an extra combination of stage 3 as well Much "noise" known as small field perturbations in random directions, is present during phase 1. This is because of the random motion of the electrons in all directions, as the addition of the excess energy to them essentially results in an increase in the average electron's kinetic energy and increases the violence and frequency of their collisions with the lattice and with each other.

The second stage is the expulsion of the electric and magnetic fields to the exterior of the conductor, and the expulsion of the excited electrons as axial currents (on the average) to the surface. This electron movement during the second stage is still immersed in the midst of a great collision/violence among the electrons in the electron gas in the conductor. Accordingly, there are erratic electric and magnetic fields from the erratically moving charges, whose violent movements are, in fact, expelling these fields from the conductor and in all directions in the conductor. Consequently, there is much noise, distortion and scattering going on in this stage.

In the third stage, the electrons reach the skin of the conductor, resulting in a marked decrease in collision frequency and violence. The relaxation process terminates with the slower ohmic and radiative damping of the surface currents.

As an end result of the three relaxation stages, a sinusoidal charge disturbance is formed and propagated in the conductor with a phase velocity Vp of roughly 1.times.10@8 cm/sec, or roughly 10@6 meters per second. Further, this disturbance is extremely noisy. It is also moving far slower than the speed of light, hence "lingers" in a circuit after each and every stimulation, directly adding noise to slightly succeeding "signal stimuli." The "signal" moves down the conductor at nearly C, the velocity of light in space.

The net result in a continual digital process is that the 3-stage relaxation phenomena continually generates lingering noise signals in a circuit. This noise is continually produced both when signals are initially recorded on a conductor, increasing the noise in the signal actually recorded, and again when the conducting medium is later optically re-stimulated to detect the recorded "signal and noise". Examples of conducting media are audio compact disc, CD-ROM (read only memory), video laser disc, photo-CD and photgraphic film. The net result is that continual relaxation noise is added to both the recording and playback stages of any recording process utilizing such a conducting medium. Relaxation noise is also added to any signal translated down or in a conductor and through circuits.

In searching prior art that disclosed magnetic and/or modulated EM devices designed for processing or clarifying conducting media for the purpose of reducing relaxation noise, no references were located that either disclosed or anticipated the present invention.

SUMMARY OF THE INVENTION

The device is a housed magnetic unit that, when electrically activated by a switch and motor means, creates a modulated EM beam or field that dampens and reduces electron relaxation or linger noise in a recorded conducting medium as the conducting medium passes through the EM field.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE INVENTION

The method and apparatus or device of the present invention is discussed hereinafter in terms of 3-stage relaxation noise actually introduced to all signal conducting media by the recording process, and again introduced in the playback from such recorded conducting media.

First, the sharp distinction between the first and second relaxation stages is removed. The moment the charges present in the electron gas in a conductor are excited with excess energy from the leading part of the incoming signal stimulus, excess fields exist on the electrons, directly combining with the E- and B-fields already in existence. Consequently, stages 1 and 2 are considered combined. In other words, even in stage one, a strong component of the excited fields is attempting to axially eject or expel electrons from the conductor, while other strong fields oriented within the conductor are affecting the entire electron gas, increasing its collision frequency and noise. Axially, there is less collision damping, so on the average an axial movement toward the surface results. Axial expulsion is a radial effect.

Next is the effect of an additional magnetic field from an external magnetic pole, which is what the present invention provides. The magnetic pole, for example, may be fairly localized in the case of recording signals and replaying signals, or it may be distributed in a "cover" or "blanket" covering the outside surface of the conductor. In the case of flat conducting plates, the blanket may cover both sides.

When any field element attempts to emerge from the conductor, or can be decomposed into longitudinal and axial components where the axial component attempts to emerge, it is directly coupled to one or more axially (on the average) moving electrons within the plate, which constitutes the source or sources of the fields. The source electrons are also attempting to move to the surface themselves. However, the strength of the electron-associated magnetic field will be altered, affected and resisted by the externally introduced modulated EM field of the present invention.

The net effect of the magnetic field, as produced by the present invention, is to induce damping and "magnetic braking" of the electrons and damping of their fields. In addition, a moving electron in a magnetic field is forced to turn away from its path, again increasing damping. In the externally introduced modulated EM field of the present device, the axially (on the average) moving electron is forced to develop an electric field gradient at right angles to its (on the average) axial movement, and "back against" the "linger noise" stimulus. In short, the electron develops a "back EMF" from all of the other electrons in the gas, which resist its movement and damp it. This dampens the electron's axial component, consequently its movement and concomitant relaxation "stage 1" and "stage 2" noise, resulting in a materially reduced relaxation noise.

The result of the use of the present invention, is that as the electrons continue to violently alter their directions due to collisions, they are continually damped by the modulated EM field created by the device. Consequently, the erratic movement of the electrons are constrained, their velocities are lowered, their collision frequency is diminished, and relaxation noise is reduced, compared to the situation where no external EM field is present. The net result is a reduction of relaxation or linger noise resulting in clarifying of audio and/or visual signals from the conductor.

When the external modulated EM field of the present invention crosses the relaxation excitation E-fields of the conductor, longitudinal components on the electrons, in either direction, are produced which contribute to the overall damping. The fundamental principle is that, as the electrons increase their kinetic energy during stage 1 and stage 2 of the relaxation time, that increase is being resisted by a magnetic braking/damping effect, and the axial ejection and noise components that continually develop are damped by the introduced EM field.

This results in a reduction in the production of both immediate and linger noise. It is the mirror symmetry of the "magnetic brake" effect. The excited electrons try to move faster, in effect creating "eddy currents" in the conductor. Moving in the fixed magnet's modulated EM field, these "eddy currents" exert a magnetic repulsion force upon the magnetic pole, which in turn exerts a braking effect back upon the "eddy currents" themselves. This latter effect constitutes noise reduction in the conductor.

The end total result of the use of the device of the present device is:

1. Reduction of the velocity and kinetic energy of the electrons during coupled phase 1 and phase 2;

2. introduction of substantial additional damping upon the harmonic damped-oscillation relaxation noise that results in phases 1, 2 and 3,; and

3. substantial reduction of the overall relaxation noise in the system, in the resulting conducting medium, and in the resulting playback from the conducting medium.

The device directly reduces the relaxation noise in all conducting media which involve EM effects in recording and playback, and in transmission of signals. In any operating system, whether recording or playback as such is being performed or not, the present device directly reduces the continuously-forming "lingering relaxation noise" from signals that have previously occurred, and that are actually slower-moving charge disturbances constituting relaxation noise in the system's operation. The relaxation noise is also a power loss from the signal. Reduction of the signal power being lost in the system constitutes effective enhancement of the noise-free power transmitted by the system.

Application of the device increases the signal-to-noise ratio by dramatically reducing the lingering relaxation noise that is continually produced in: 1) systems operation; 2) the conducting medium; and 3) detection, amplification, and playback from the conducting medium. Media conductors or conducting plates that the apparatus may be applied to are audio compact discs, CD-ROM discs, photographic compact discs, video laser discs, motion picture and still-camera film of all types, x-ray film, optical media, and other medium which involve EM effects in recording and playback and in the transmission of signals through normal circuitry and conducting plates. Video, audio and digital tapes also benefit from the present invention but conducting tape must be treated with the device before recorded upon.

The systems may be any EM system such as electrical, electro-optical, magnetic, and magneto-optical systems. The continuously-formed lingering relaxation noise is a direct part of the so-called "standard noise" in the system.

When the device is applied to a conductor, such as an audio compact disc (CD) that normally produces playback distortion as a result of relaxation noise, the distortion is reduced and there is an improvement in sound quality with improved clarity and sharpness of the music or other such sounds. When the apparatus is applied to a medium that has a visual expression, such as a CD-ROM, Photo-CD, video laser disc or photogaphic film, there is improved visual effects with greater clarity, sharpness and color to the resultant pictures and photographs.

One embodiment of the invention is a device comprised of a pair of permanent magnets in an orientation in which their like poles, i.e., north or south, are in a facing and repulsing relationship. A coil of wire is then wound around the pair of fixed magnets in an orientation orthogonal to both the interface between the facing magnets and their north and south poles.

A motor means and electric supply means is provided for creating a pulsed current characterized by sharp voltage spikes to the coil of wire creating a modulated EM field while also producing a means for spinning the conducting medium when placed on a spindle that is driven by the motor means. A far greater effect is given by the brushes of the motor means when DC current is applied at a constant rate. At the same time, the motor means provides a more constant means of maintaining optimum rotation of the spindle thus exposing the conductor to the constant effect of the EM field.

The molded spindle allows for improved centering and stability during rotation of the conducting medium. The conducting medium is oriented to the device so that its plane is parallel to a plane running through the north pole orientation of the magnets. As the conducting medium passes through the modulated EM field, the electrons of the conductor are effected by the field, thus reducing the relaxation noise.

The device is housed in a container, such as a molded plastic housing, to maintain magnetic unit placement and to allow for greater penetration of the modulate magnetic field by the magnetic unit and with greater effect on the conductor.

One application of the device of the present invention is in clarifying sounds emitting from an audio compact disc. Compact discs are comprised of an aluminum surface encased in a plastic coating. The disc itself is composed of a very thin piece of stamped aluminum, which is the conducting medium, encased in plastic. The thin aluminum layer is the active ingredient that contains the recorded data.

A second application is in the clarification of compact discs such as video laser discs, photo-CDs and CD-ROMs. Processing of visual compact discs produces a clearer, sharper, brighter and more colorful image both on the computer screen and in a photo image.

A third application is in the clarifying of photographic films of all types. Exposed film that has been clarified before developing the film produces a consistantly clearer image than film that is unclarified.

Referring first to FIG. 1, 10 is a device comprised of a magnetic unit 12 which is further comprised of a pair of permanent magnets 14 and 16 orientated with like poles in a facing, contacting and repelling relationship and fused with an adhesive means 18 forming a seam with joined magnets 14 and 16 producing a shaped magnetic field 22. Magnets 14 and 16 are oriented with their north poles in an abutting relationship, although the magnets may be abutted using their south poles.

FIG. 1 further shows a coil of wire 20 wound around magnets 14 and 16 of the magnetic unit's out facing poles with coil 20 having an orientation perpendicular to the plane of the interface between magnets 14 and 16. Coil 20 may consist of 150 to 300 turns of a #34 enamel-insulated high temperature wire, with 250 turns preferable. Magnetic field 22 is shown emitting above adhesive seam 18 of magnetic unit 12.

Also shown in FIG. 1 is circuitry 3 for providing an electrical supply to coil 20 of magnetic unit 12 used in apparatus 10. Circuitry 3 is comprised of a DC motor 5, a controlling switch 7, either a 9 volt DC battery or a DC power supply 9 and connecting wire 11 to coil 20. DC motor 5 also provides a means for rotating spindle 33 seen in FIG. 2. In the alternative, electrical power may be provided by a 120 volt AC power supply 13 which is reduced to 9 volts by passing through a 9 volt AC to DC convertor or power step-down unit 15.

FIG. 2 is a perspective view of a housing 31 which contains apparatus 10 and its components. Seen emerging from the top of housing 31 is spindle 33 for the placement and orientation of conducting medium 24. Spindle 33 emerges from the top side of housing 31 for ease of placement of the conducting medium. Closure of switch 7 creates a modulated EM field 22 simultaneous to the spinning of conducting medium 24. As the conducting medium spins, it passes through field 22 thus

producing the desired effect on the conductor.

FIG. 3 is an inside view of the bottom half of housing 31 showing compartments, A-1 and B-1 separated by a divider 35. Compartment A-1 is adapted to fit over compartment A-2 of the top half of housing 31, seen in FIG. 5. Compartment B-1 contains a 9 volt DC battery or DC power supply 9, space for switch 7 and space for motor 5.

FIG. 4 is a perspective view showing the orientation of conducting medium 24 to spindle 33 and motor 5.

FIG. 5 is an inside view of the top half of housing 31 showing compartments A-2 and B-2 separated by divider 37. Compartment A-2 contains magnetic unit 12 with connecting wire 11 from coil 20. Wire 11 passes through a recess in divider 37 and into compartment B-2 to connect to motor 5 and switch 7. Compartment B-2 contains motor 5 and a side wall of B-2 contains a recess for switch 7. Beneath motor 5 and on the roof of the top half of housing 31 is an opening for the emergence of spindle 33.

FIG. 6 is a side view of housing 31 showing the relationship of the various elements to each other. Magnetic unit 12 is located in compartment A-2 of housing 31. Connecting wires 11 connect coil 20 to a 9 volt battery or AC to DC convertor 9 and motor 5. Spindle 33 is connected to motor 5 and emerges through the top of housing 31 to accept conducting medium 24. Conducting medium 24 is shown in close proximity to magnetic unit 12 and oriented in a plane perpendicular to the plane of intersection of magnets 14 and 16 so that when apparatus 10 is activated, the rotating conductor 24 will pass through the modulated EM field 22.

EXAMPLE I

An analysis of an audio compact disc was carried out with the test completed using a Schlumberger 1510 Audio Spectrum Analyzer to display real-time fast fourier transform (FFT) spectra of the sound, a Tektronix 465B dual-trace oscilloscope to display phase differences between left and right stereo channels as well as waveform shapes, and a Leader LMV-185A 2 channel AC Millivoltmeter to simultaneously read the amplitude of the left and right stereo channels. The spectrum analyzer has a frequency range of up to 25 khz, a dynamic range of 70 db, and an absolute range of 100 db using attenuators, and an accuracy of 0.1 db and 1/256 of the frequency range selected. All measurements were made using the 25 khz range. The oscilloscope has an upper frequency range of 100 mhz. The test CD was played on the Denon DCD-1500 II compact disk player connected directly to the above instrumentation.

The test CD, CDP 7 46446 2, DIDX 2249 Stereo, UK: CD-PCS 7078, manufactured by Capitol Records, otherwise known as the Beatles: Abbey Road album originally recorded in 1969 and digitally re-mastered in 1987 for CD, was subjected to the above equipment and technique. Spectral measurements at a 00:24 interval was made on track #7, a selection known as "Here Comes the Sun".

Track #7, at a 24 second interval, is exhibited in Example I as a series of bar graphs in diagrams 1-8. The bar graphs simultaneously show the relative loudness in decibels "before" and "after" clarifying of the device. Each pair of bars represents the relative loudness of frequencies between 100 hertz and 25600 hertz of Track #7 time 24 seconds of the audio CD analyzed.

Diagram 1 shows the entire spectrum from 100 to 25600 hertz in 8 frequency bands as labeled at the bottom of the diagram. It is noted that each frequency range except for 200 to 400 hertz is about 1 or 2 decibels louder after processing by the device.

Diagrams 2-8 display the same data in more detail showing a larger number of smaller frequency ranges in intervals of only 100 hertz each. Because frequency ranges are smaller there are more variations in the data, however, the readings show the trend of being 1 to 2 decibels louder after processing.

It is noted that each of the spectral differences as well as the average spectrum difference follow a profile demonstrates the effect that clarifying by the instant device has on the CD.

EXAMPLE II

An analysis of an audio compact disc was carried out by first recording "The Best of Mike Olfield--Elements", track "Portsmouth" without clarifying the CD, on a hard drive using a WAV file of Voyetra's WINDAT software with a sound card connected to a CD-ROM's audio output. The recording was in mono at a sample rate of 44100.

Following the first recording, the CD was then clarified, using the device, by placing the CD in the modulated electormagnetic field of the present device for 10 seconds on each side followed by again recording the CD using the above technique.

Using the WINDAT program, the "before" clarifying and "after" clarifying recordings were trimmed so that application of the device could be easily compared with non-application. Ten second and 0.25 second excerpts were used. The ten second excerpts were measured from the point where sound began to come off of the CD. The 0.25 second excerpts were taken from a consistent point within the body of the recording.

The sound files were converted into graphics using two Shareware programs: Screen Thief and Blaster Master. The recordings were loaded into Blaster Master individually and the graphical representation of each recording was captured using Screen Thief. The graphics of the sound files were then laid down and compared using Deluxe Paint II Enhanced.

The graphical representation of the sounds, in Diagrams 9-11, is based on amplitude and time. The left side of the graphic is the beginning of the recording, and right side is the end. The beginning of the graphic is defined as the point where sound began showing up on the graphic.

Diagram 9 illustrate a 10 second comparison of the unclarified with the clarified CD. The waveform represents amplitude. It is noted that waveform A, the unclarified sample, is taller than waveform B, the clarified sample.

Diagram 10 is of the same recording but compares exclusively unclarified, partial waveform C, unique to waveform A, and clarified partial waveform D, unique to waveform B. That is, all of the points in the unclarified graph, waveform A, that correspond to points in the clarified graph, waveform B, have been erased resulting in waveform C, and all of the points in the clarified graph, waveform B, corresponding to the unclarified graph, waveform A, have been erased, resulting in waveform D. This technique leaves a graph showing the data that is unique to the recording in question. Thus, in Diagram 10, the graph labelled "Exclusively Clarified", the visible lines show data that is unique to the clarified recording, and the "Exclusively Unclarified" graph shows sound or noise that was no longer present after clarification.

Diagram 11 illustrates a 0.25 second comparison of the unclarified CD, waveform E, with the clarified CD, waveform G. Waveform F is the exclusively clarified and shows what is unique to waveform G. A graphic of an exclusively unclarified waveform was eliminated because interest was in the clarified waveform and what is unique to it.

Three criteria were used in analyzing the graphs of Diagrams 9-11: Response Time, Noise level and Density. Response Time refers to "when the sound starts", a key factor because the CD excerpt recorded was timed from the moment that sound began recording off of the CD. The position of the remaining material recorded is dependent on the accuracy of the starting point. In the ten second excerpt of Diagrams 9 and 10, there were no measurable time discrepancies, as the graphs matched up as represented in the Diagrams with the peaks in the sound occurring in the same places throughout the sample.

The 0.25 second excerpts showed a lag time between unclarified waveform E with clarified waveform G. As many of the peaks of waveforms E and G as possible were matched-up and then compared to how much "extra" sound was left at the beginning. By comparing the length of the sound to the length of the whole sample, it was determined that the unclarified 0.25 second excerpt was lagging behind the clarified excerpt by about 0.01 second. A small discrepancy at the starting point would not be visible on the ten second scale, but on the 0.25 second scale is noticeable.

In terms of Noise Level, the unclarified sample was "noisier" in both excerpts, ten second and 0.25. By noise level is meant, that overall, the unclarified sample consistently had several peaks where the volume line went further than the corresponding volume line in the clarified sample. This lower level in the clarified sample is the result of a reduction of "noise" level in the clarified sample. Extraneous noise makes the overall signal noisier and less clear. The clarified sample has an improved and smoothed out dynamic because of a reduction in noise level.

Density is defined as the solidity of the volume or amplitude lines rather than the range of the lines. Comparison of the volume lines of waveform A, unclarified, with waveform B, clarified, shows waveform B to have a much more consistent volume level than waveform A. Increased Density gives greater consistency to the CD, producing a much fuller sound.

EXAMPLE III

In Example III, the identical technique used in Example II was duplicated. An analysis of the audio compact disc, "The Cross of Changes" by Enigma, track "Return to Innocence" was carried out by first recording, without clarifying the CD, on a hard drive using a WAV file of Voyetra's WINDAT software with a sound card connected to a CD-ROM's audio output. The recording was in mono at a sample rate of 44100. Following the first recording, the compact disc was then clarified, using the device, by allowing the CD to spin for 10 seconds on each side followed by again recording the CD using the above technique. The analysis technique as described in Example II was then completed.

Diagram 12 illustrates a ten second excerpt comparison of waveform A, unclarified, with waveform D, clarified. Waveform B is exclusively unclarified, and unique to waveform A. Waveform C is exclusively clarified and is what is unique to waveform D of the sound track. Waveform A, the unclarified sample, is significantly different than waveform D, the clarified sample.

Diagram 13 illustrates a 0.25 second comparison of the same recording of unclarified waveform E with clarified waveform G of the CD. It also shows exclusively clarified waveform F, demonstrating the unique difference between waveforms E and G.

Response Time, Loudness and Density were analyzed. In the 0.25 graphic of Diagram 13, the Response Time of waveform G is slightly ahead of waveform E, indicating that sound from the recording began sooner than in waveform E. The amplitude lines of waveform G are slightly reduced overall in comparison with waveform E, resulting in a reduction of Noise Level. The Density of waveform G is much greater than in waveform E, especially in the last one-third segment of Diagram 13.

EXAMPLE IV

A Photo-CD was analyzed both "before" and "after" passing the CD through the modulated eletromagnetic field of the device to determine specific changes in the retrievable data from the CD. The method and steps used to derive and quantify the effect that clarifying had on the conductor was determined using the following method and steps:

1. A demonstration Photo-CD sampler, produced by Kodak, was down loaded to the hard drive of an Apple Centris 650, 25 HRZ, 6800040 motherboard and a new file created and properly designated as "before". The photo-CD had not been clarified by the device. Images were transferred to a commercial graphics software program, PhotoShop, developed by Adobe Software.

2. The Photo-CD was removed from the ROM and treated with the present device by spinning the CD on each side for 15 seconds. The CD was then down loaded to the hard drive and a second new file created and properly designated as "after". The images created were transferred to the PhotoShop graphics software program with file separation maintained at all times.

3. Print number 3 of the Photo-CD list, contained in the "before" or unclarifyied, was brought to the screen and a text translator was used to convert the picture to post script computer language. Picture number 3 represented a photo image that measured 21/2.times.13/4 inches, using 132 LPI, 72 DPI and utilized approximately 250K of memory. Following the text translation process to convert the small image to post script, it was then saved to a new file. Following the conversion, there were 360 pages of post script computer language created to describe the image number 3.

4. The identical process as described above was used to create a post script file for the image following use of the device on the photo-CD. The "after" or clarifying effect resulted in 348 pages of post script computer language.

5. The first 16 pages of post script language was specific to language to program the printer. The balance of the pages in both cases was post script language to describe the specific image that was converted. The first 4 pages of both files were then converted into text files using Wordperfect 6.0. The process of converting the post script files to text files was for the specific purpose of utilizing a specialized software program that could compare the text language of both files. The process of converting the first 4 pages of both post script files to text files took 25 minutes and resulted in the generation of 101 pages of new text language. The ratio of pages of text converted from post script is approximately 1 to 25. If the entire post script files (354 pages average) were converted to text file using the same ratio, it would require approximately 8,850 pages of text file to fully describe a single 21/2.times.13/4 inch colored image.

6. The software used to simultaneously compare the text in the two files, DocuComp II, version 1.05, is a product of Advance software, Inc.

7. The first 4 pages produced a total of 101 pages of text file. When placed into the DocuComp file, it resulted in the following summary of information changes: The 4 pages represent slightly more than 1% of the total data available from each image. If the entire 708 pages were converted and analyzed, it would take considerable memory capacity and about 37 hours (4 pages of each file takes 25 minutes) of computer running time to analyze 708 pages of post script computer language.

8. Four pages from each file generated a total of 56 material changes, on the average, resulting in over 5,000 changes for the entire image when "before" clarifying was compared to "after" clarifying.

9. The "before" unclarified file, resulted in 53,336 bytes of information The "after" clarified file version, generated 50,521 bytes of information. The comparison represents a difference in information retrieved equal to 5.7% less for the clarified file.

Clarifying the Photo-CD with the device realigns the data into a tighter format by reducing superfluous data. Each Pixel has a "halo" or influence zone. Exposing the pixel to a modulated EM field reduces the halo by suppressing electron activity or relaxation noise thus causing the pixel to be sharper with improved clarity. The photo-CD manufacturing process can produce residual color around each individual pixel referred to as pixel residual or bleeding. When a pixel, represented by post script and text script, is sharper, it does not require as much information to accurately describe or define it. When a pixel halo or influence zone is reduced, it requires less information to describe the data. In Example IV, 5.7% less information was required following clarifying by the device, at the same time improving the image to describe the same segment of the picture.

The analysis process of converting each image to post script and then to text is accurate. Changes created by treating a photo-CD with the present device can be demonstrated by a computer comparison of the information generated from both images.

Diagram 14 is a Summary of Post Script Changes with a list of differences between the "before" and "after" application of the device to the photo-CD.

EXAMPLE V

Using the identical technique and steps as described in Example IV, steps 1-9, a second Photo-CD, Nature's Way, published by Gazelle Technologies and produced by Kodak, was tested "before" and "after" application of the present device. In this Example, the original bytes numbered 74,151 before clarifying with the device. After clarifying, the number of bytes were reduced to 70,214 resulting in a 5.6% byte reduction.

Diagram 15 is a Summary of Post Script Changes with a list of differences between the "before" and "after" application of the device to the photo-CD.

Diagrams 16 and 17 are black and white, "before" and "after", copies of color pictures of the photo image of the photo-CD, demonstrating the effect that clarifying the conducting medium has on the comparable results.

THE LAW OF THE SQUARES

This introduction, which shows that work out of star ship Ezekiel MK V, took three people to hold it out to film it. At this date, John Thomas in Rochester New York holds it at his home.

JOHN A. THOMAS Jr.

Vice President, D.I.S.C.

1 Mr. Thomas has a technical background in electricity and process control.

2 He has studied such varied topics as UFO's and Ancient Technology that has been lost or forgotten.

3 He has carried on the efforts of Mr. William Sherwood, formerly Professor Searl's contact and helpmate in the ***National Space Research Consortium. (NSRC).***

4 He first contacted Professor Searl in 1990 and since that, time has printed and distributed his books on "***The Law of the Squares***."

5 John has been a student of Professor Searl and has come to an understanding of "***the Square Technology***" which is the basis for the ***Searl Effect Generator (SEG)*** and the ***Inverse-G-Vehicle (IGV)***

6 John is presently Vice President of the ***Direct International Science Consortium*** (***D.I.S.C***.) and is Technical Representative for Professor Searl.

7 Prof. Searl promised John that he could ride in a small hut pulled behind the ***IGV.***

1 This is the man who owns the technology termed the **SET**.

2 The technology sits in his brain; therefore it cannot be own by anyone else.

3 What he states is that he is prepared to form a group to develop this technology.

4 That statement means that his dream at this time is in the world of fantasy

5 But that dream can and has been defined by structure and function

6 Therefore, it is legal for him to state that he has a concept for research and development, and no other person living or dead has the right to that statement.

7 It is known that others make belief that they own it, how can them when they have no idea how to do it.

7 The concept herein: shall be defined as being a ring and a roller set.

8 The purpose of that set is to demonstrate proof of a phenomenon herein termed the '***Searl Effect'***

9 Proof of the '***Searl Effect'*** being accepted when the roller operates non-stop for 3 days or greater.

10 The term '***operate***' refers to that a roller; without any form of assistance commences to rotate around a ring, and continues to do so; without any form of assistance from any other source other then itself.

11 This definition defines the concept for research and development.

1 Up to this moment in time in which I had been living at No. 13 Blackburn the Following people were involved.

Luis Jarillo found John Searl and the accommodation at No. 13 Blackburn.

2 That paper work shown on the first page is the scale model of ***Starship Ezekiel MK.V***.

3 Three people against wall just yards are holding it from ***No. 13 Blackburn*** protects against the wind.

4 I myself work out the structure than cut it out to check that my figures were correct.

5 That cut out is held in John Thomas hands in Rochester. USA.

6 These are those who were encouraging me to return to this work

Miss Susanah N. Mutua.

7 First picture is Luis who found me as a lonely down hearted person who had been destroyed by his own family.

8 He found the home in which that picture was taken

9 The next picture of Susan is that person who gave me her home to live and work so that all humankind could benefit in the end.

10 This next picture is Dominic Mutua son of Susan who helped me from time to time with the heavy lifting work.

11 That is basic the main story, from the time my first wife destroyed my life and work.

12 Susan became my whole life; I work many hours to recover this work under terrible pain conditions.

13 All this based upon faith that this time I would succeed to the market place and Susan would become my wife.

14 Faith that here at number 13 Blackburn would be my home, and never again would I be lonely and homeless.

15 Only time will tell the truth what happen to this work.

16 This move to number 13 Blackburn cost me thousands of pound loss.

17 Equipment again was needed to be replaced so I could undertake this work.

18 Susan went out of her way to help me upon that issue, where no one else made the offer.

19 Latter another big problem occurred which would have ended this work, but John Thomas did rush in to save the day.

20 Teams form and then disappear.

21 WHY?

22 The answer is quite simple. A person informs us that they will have millions in a month's time and wish to invest a million or more to develop this engine.

23 The group start to work hard to get ready for full speed ahead as soon as the funds arrive.

24 Alas, as always, no funds came, and it is only natural that the hard work put into this without payment cannot continue.

25 Therefore, the team slowly breaks up, as it had no purpose to continue if no product could be produced.

26 This class of work clicks into millions of £'s or $'s to develop it to a point in which it could be mass-produced.

27 Without that funding there is almost nothing I can do, except to write my life story, which is the Law of the Squares.

28 That is also greatly expensive to do.

29 Here are two more ladies who helped me in different ways.

30 The first was Rita a lifetime friend of Susan; she helped me with the book called the dream that came true.

31 The young lady named Joy came into my life right from the moment of her birth, at this age she was communicating with me as a full-grown adult.

32 She amazed me with her questions, which clearly showed me that she was reasoning every thing, which she was being taught at school.

33 She would give me her feelings on the subject and then ask me what I think about it.

34 Her reasoning was sound, her judgement was perfect, in reference to adult women and men who come here to talk, and she was far more intelligent. I enjoyed listening to her reasoning and judgement.

35 By the time this photo was taken, she was capable of correctly and quickly works out the answers to extremely large sums, which her mother Phyllis always complained to me that I should not give her such large sums to do.

36 However, she loved them, because she loved me so much that she put her heart and soul behind her learning with me.

37 This little woman gave me the driving force, not only to make Susan’s home lovely but also to speed up the work on this technology, and to record what I did and what was happening around me at that time.

38 In return, I gave her love and the power to learn, because she knew I would tell her the truth to all her questions.

39 Not only that, but I would listen to all her problems without getting nasty about what she had said.

40 It was a bond which is rarely seen between an adult and a child, a bond so great that it became her driving force to learn

41 If this bond is ever broken, the power to learn will also be lost for good.

42 If a child loses a bond it will result in the lost of ability to learn.

43 These books, which I hope I shall live to write will present what has happened to me and how I have responded to each situation involved.

44 However, when I am dead that may be all which is left to show the effort which I went to for support to create a new technology which would solve all of our present day problems.

45 Yet 80 % of the world’s population has no idea that there are any problems, because they fully believe without question that if there were any problems their government would solve that problem.

46 Though most people may not believe that there is any problem to worry about, but the very few who do know, many of which go to the extreme state and start to present insane activity, in place of logic thinking.

47 Like for example, Aliens will be arriving in the year 2000 to collect all you UFO nut cases and take you to a place of safety.

48 Maybe the backside of the Moon or better still on top of a mountain on Mars.

49 They are in communications with Aliens, but do not show you their transmitter or receiver so you can order one from your local shop.

50 Others are constructing large airships, arming members, and teaching them how to defend themselves and kill. This is the crap, which this planet is loaded with sadly to say but the insanity level is increasing at a much faster rate than ever before from where I sitting.

COMPONENTS FOR EVALUATION 1993.

1 ***OCTOBER 4th, 1993***, work has re-started upon my technology, now is the time to evaluate the latest components for selecting the best option for the various functions, which will be required within this technology.

2 I know there is just one person who states that people claim that I write bullshit in my books to blind readers with technology.

3 I know these people buy these UFO mags and videos and believe absolutely what they state.

4 To those people, the truth can never be accepted.

5 I do not intend to try to convince them, in **FACT,** the **TRUTH** is, and I have no intentions whatsoever of trying to convince anyone as far as it goes.

6 What I am offering to the world is a **CONCEPT FOR DEVELOPMENT** and the **FACTS**, which I can present in support of such a concept, what I actually know, and how to apply that knowledge to such a concept.

7 I can propose what components should be considered to meet each function part thereof, to arrive at the best option for success.

8 Therefore, everything stated within these books are more precise than that of the bible will ever be in **FACTS**.

9 Far more **TRUTHFUL** than the bible is.

10 It is a **BIBLE** of absolute **FACTS**, as I know them.

11 Only advancement in science and technology can actually update these books.

12 That is why there is no end to this story because it is forever extending its bonds in science and technology.

13 So let me introduce you to the latest problems, which must be solved for this technology, which has just re-started.

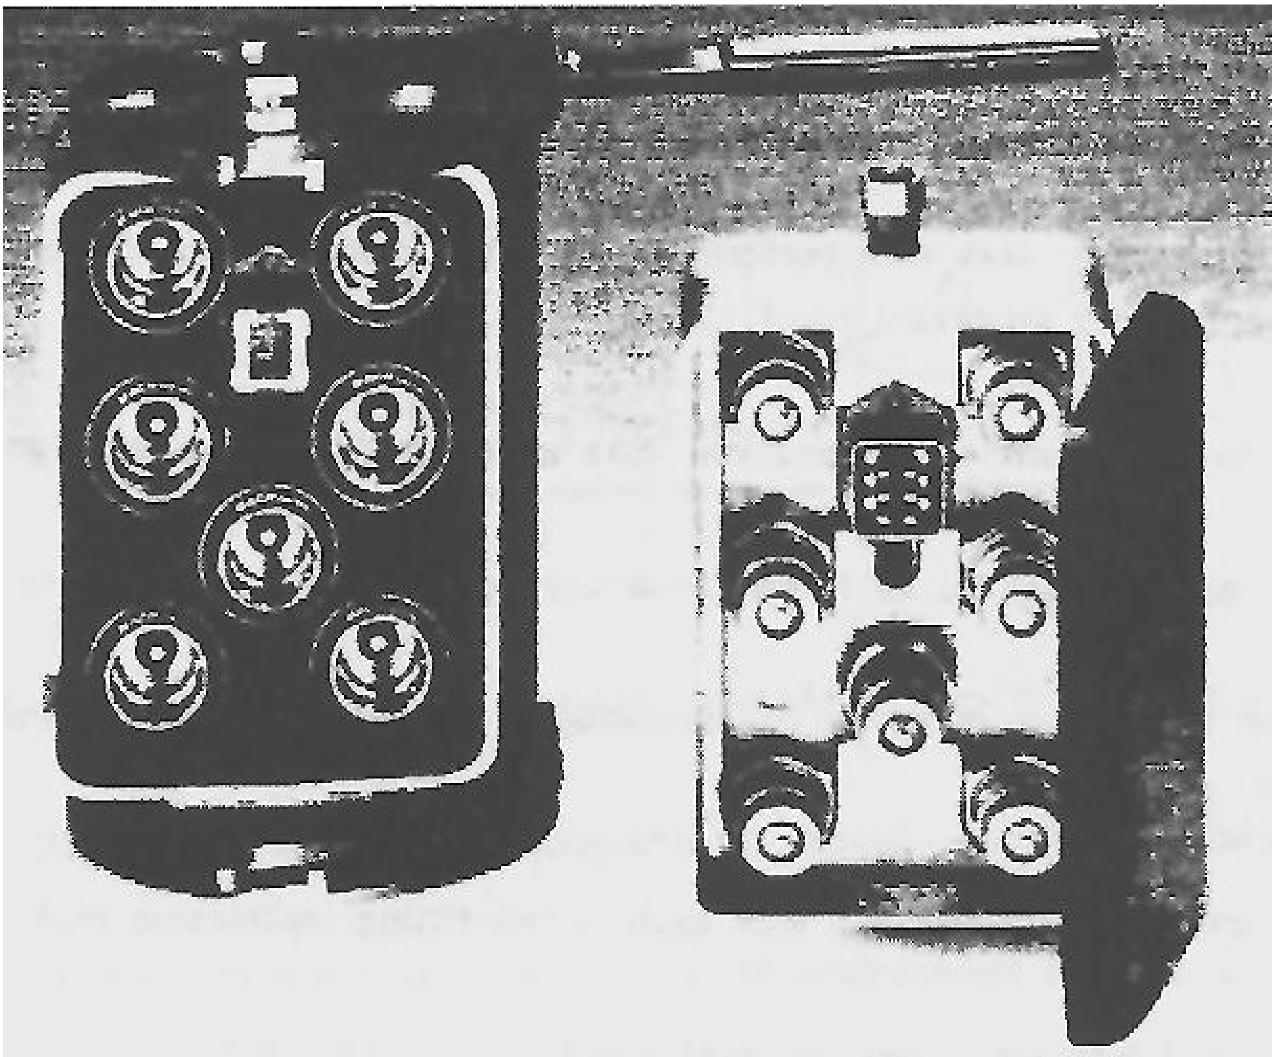
14 The hydraulic connection between an agricultural implement and a tractor as shown below is now an easier task with these Pioneer multi-couple.

15 Now such a concept could very well be applied to the slender disc project for the flight cell function.

16 In the above figure, that system connects up to seven hydraulic lines and six electrical lines in a single operation.

17 Well done!

18 Two heavy-duty die cast aluminium housings hold the quick couplings during connection.



MULTI-COUPLER SYSTEM

19 In the above figure, the quick couplings used conform to ISO standard 7241 series A.

20 It allows simultaneous connection of all hydraulic and electrical lines and offers many advantages:

- ***(1) Service pressure up to 250 bar***
- ***(2) Compact, lightweight, multi-coupler with a strong construction***
- ***(3) Simple, effective and fast connection even under severe service conditions***
- ***(4) Housing and cover for total dust and moisture protection and long service life***
- ***(5) Safe connection, even under pressure***
- ***(6) Impossible to connect incorrectly***
- ***(7) Developed with the user for the user***
- ***(8) Compatible with any equipment already fitted with standard ISO A quick***

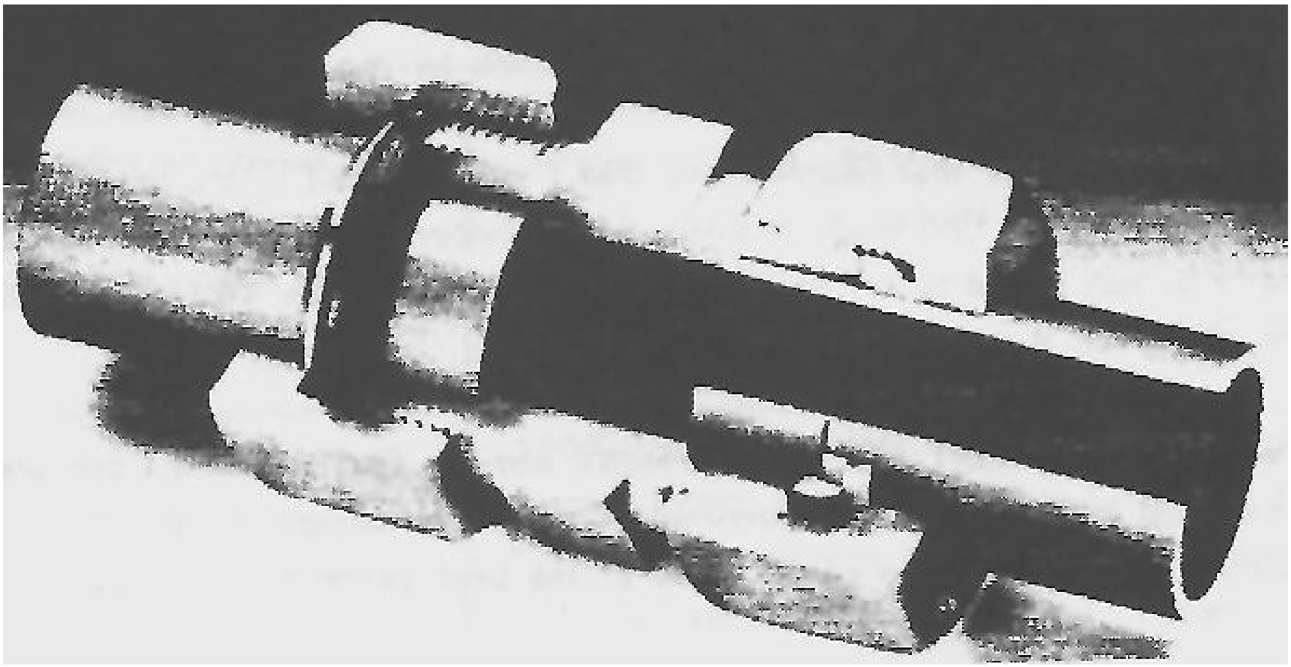
COMPONENTS FOR EVALUATION 1993.

Couplings

21 This multi-coupler system may also be used for materials handling and public works equipment, machine tools and other industrial equipment.

22 That is just one point to think about, remember that there are 64 flight cells, which must be able to function by more than just one option, there must be at least three different options of operation of these flight cells.

23 So think upon it!



EO-2 DRY TECHNOLOGY.

24 EO-2 is a new generation of leak free fittings, and forms part of a “Searl’s ***Dry Technology***” programme for the ***INVERSE-G-VEHICLE***, for a safe, clean, leak free sealing even under the most severe conditions.

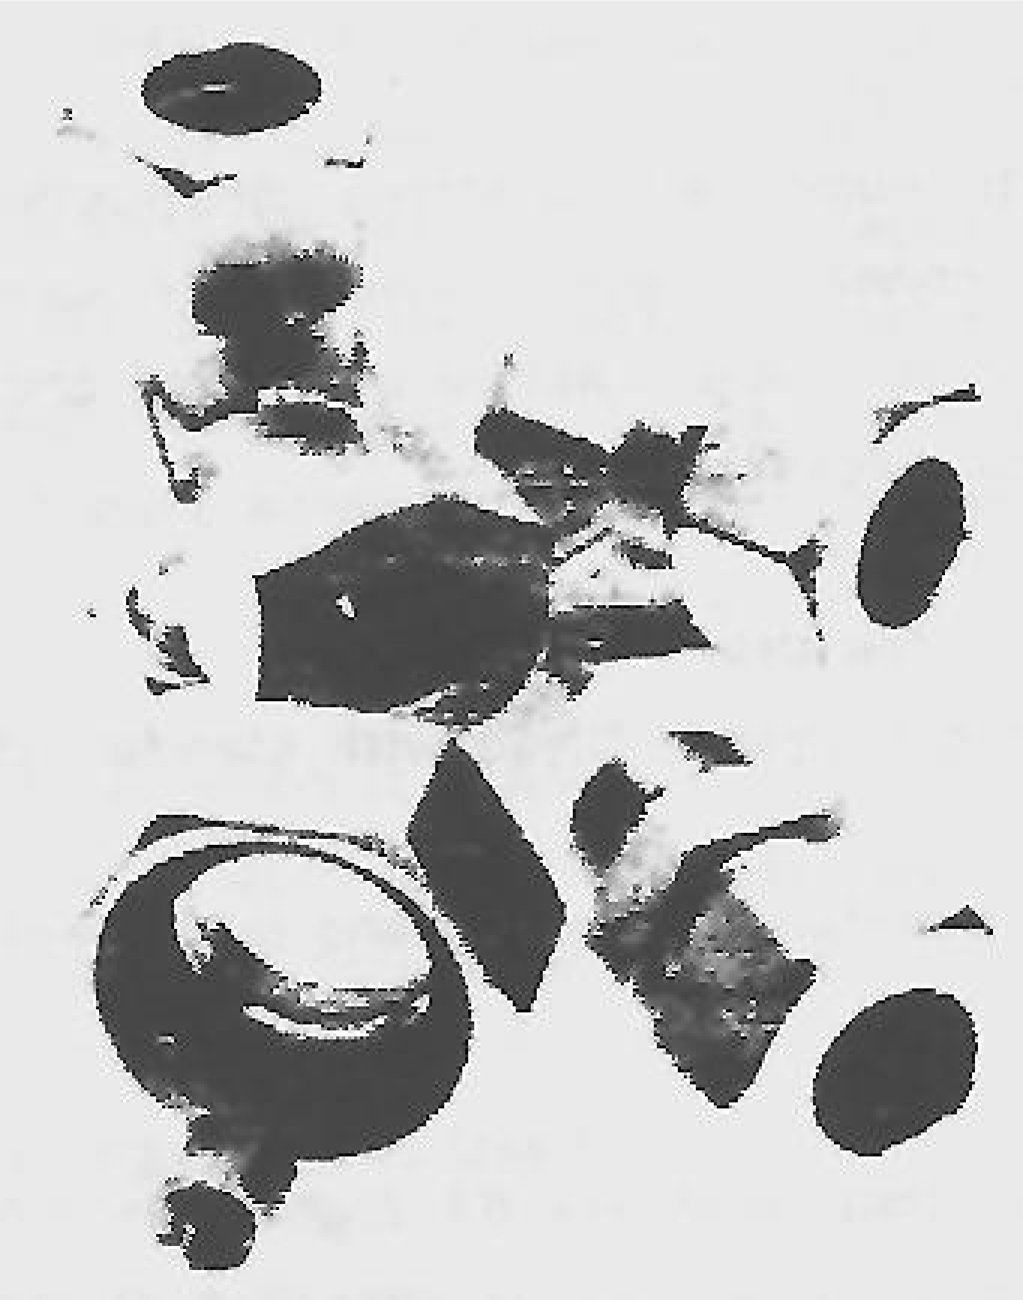
25 Conforming to DIN 2353 standard, the EO-2 bite type fitting has been completely re-engineered to feature vastly simplified assembly characteristics.

26 EO-2 incorporates soft sealing for secure, leak free performance, the number of parts has been reduced for easier handling, and stocking, which will be very important point.

27 Simple one stage assembly to block, without lubrication, cuts assembly time, two very good points to consider.

28 Assembly by torque is possible, as is full assembly by electrohydraulic tooling.

29 The nitrile rubber bonded seal on the ferrule gives all the advantages of soft sealed joints, including tolerance of surface imperfections, dirt, misalignment, etc.



EO-2 Anew generation of fittings with soft sealing, allowing leaks to be prevented more effectively than ever before

30 The sealing lip blocks the only possible leak path in the fitting, optimising performance.

31 An integral bite ring gives the mechanical joint onto the tube.

32 To make the use of EO-2 even easier, the soft seal ferrule is factory fitted into the body nut to operate as a single unit, making it impossible to lose ferrules or assemble them the wrong way round.

33 Another unique advantage is that the nut stays where it is placed on the tube, instead of sliding to the lowest point or off the end, as no doubt that many of my readers can well appreciate the ruddy nuisance it is when you are trying to fit a pipe

In a hurry, to find that the nut is not where you want it.

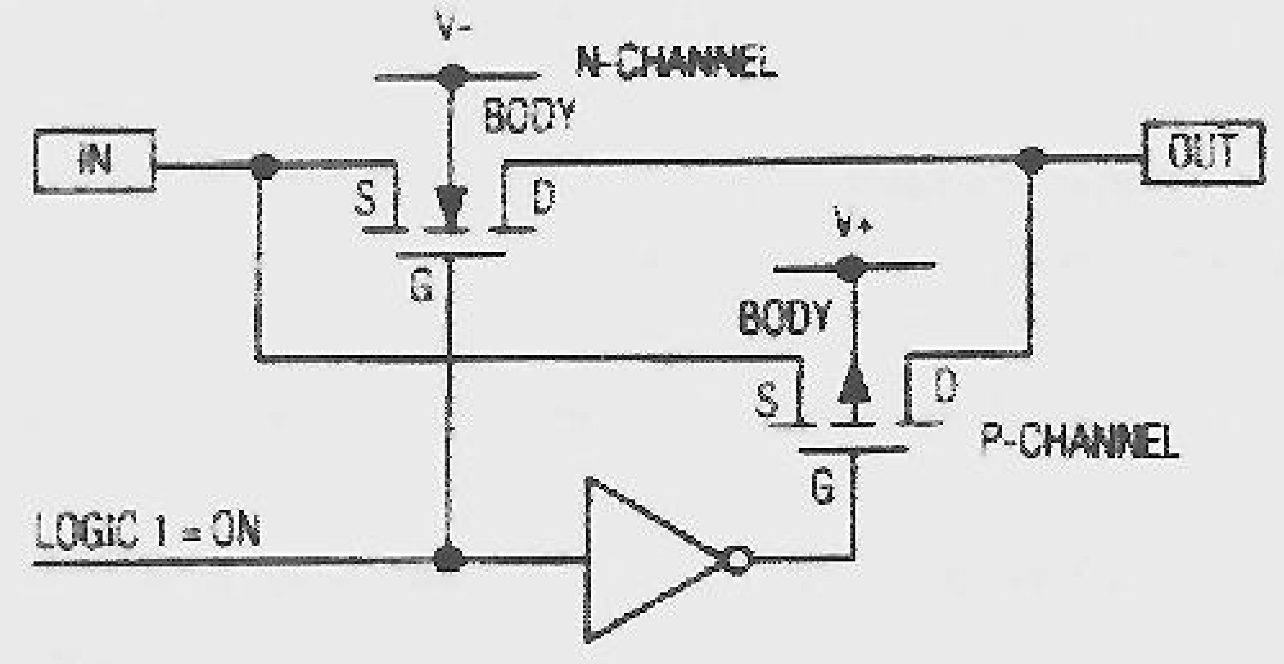
34 I know what you say even if it is only mentally, when you are up 50 or more feet in the air, and that nut is lying on the floor.

35 You need not be ashamed of that fact, there are many more members of the same Club, you are not alone.

36

EO-2 can solve problems for applications where assembly difficulties have been experienced, boy they can state that again, or leaks have led to costly rework, cleaning up, or warranty charges.

37 FAULT-TOLERANT CMOS MULTIPLEXERS OFFER "BEST BUY" PROTECTION



THE TRADITIONAL CMOS ANALOG SWITCH IS A TRANSMISSION GATE

38 All analog multiplexes act as the solid-state equivalents of digitally controlled rotary switches.

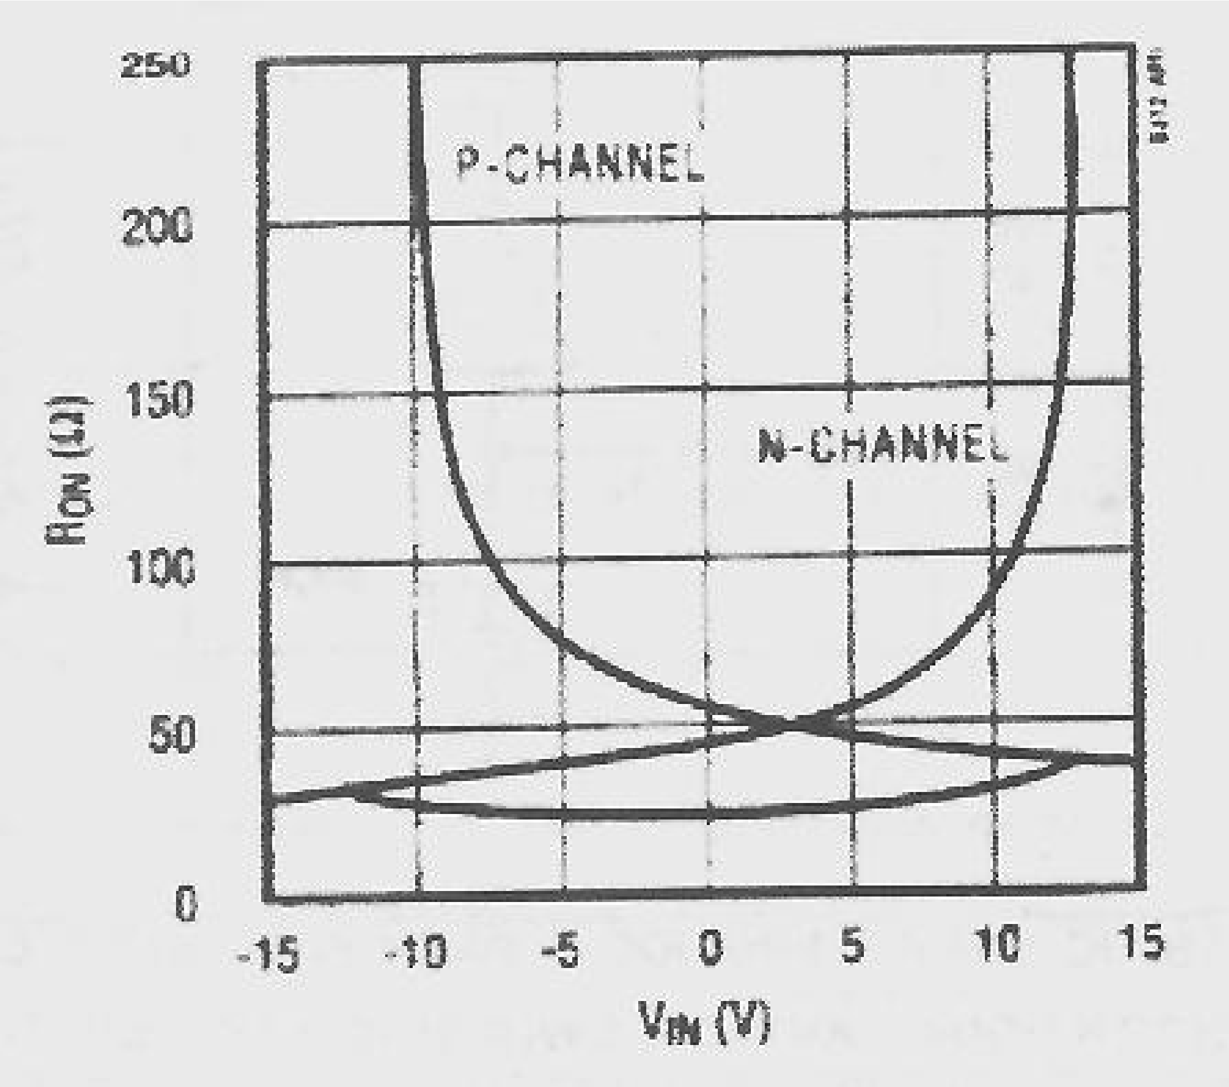
39 However, multiplexes at the interface between an electronic system and its environment have an additional function - they act as insurance policies against malfunction and damage.

40 As a designer, I may control the system, but input multiplexes contend with everything outside the system - poor installation, careless operators, and electrical noise.

41 They must operate correctly in the presence of ground loops, electrical interference from motors and engines, and unintentional inputs such as 240 VAC.

42 In my following discussion, a particular design (the serial MOSFET switch) comes to mind, as one of the devices which emerges as the most economical choice in

overcoming these problems.



WHOSE ON-RESISTANCE VS. SIGNAL VOLTAGE CHARACTERISTIC EXHIBITS A DOUBLE HUMP AS SHOWN

43 Other designs offer over voltage protection alone, but only, at least to my knowledge, the serial-MOSFET approach combines overvoltage and fault tolerance without the need for external components.

44 The switches in common multiplexers have been designed the same way for nearly twenty years: each consists of an n-channel and p-channel MOSFET connected in parallel on a SILICON substrate, and driven with opposite-polarity gate-drive voltages as shown in my figure on page 11.

45 This connection provides a symmetrical signal path through the parallel source-to-drain resistances, producing a characteristic double hump in the curve of on-resistance vs. input voltage as shown in my second figure above.

46 Many designs minimise this effect by driving the body connection of the n-channel MOSFET with signal voltage.

47 The presence of each device polarity guarantees that at least one of the two MOSFETs will conduct for any input voltage between the supply rails.

48 Thus, the multiplexers can handle any signal level that falls between the rails.

49 A multiplexer switch ceases to be a switch, however, when signal voltage exceeds either supply rail.

50 Each switch includes two parasitic diodes, intrinsic to the MOSFET source and drain structures, which provide current paths to the rails, at this precise time.

51 I cannot put in the figure that I want, the drawing is far too large to scan in here, so hopefully I can find a way of reducing the size of it and add it at the back of the book, if I don't forget it.

52 Both diodes are reverse-biased during normal operation, but any signal excursion beyond the rails applies forward bias to one of the diodes, clamping the signal at 600 mV beyond the rail.

53 Because the diodes are present when power is removed, they also clamp (at ± 600 mV) when the rails are at zero volts.

54 Parasitic diodes provide a useful clamping function, but they also introduce problems.

55 Excessive current in the diodes can cause overheating and damage in the signal source as well as the multiplexer (figure 3)

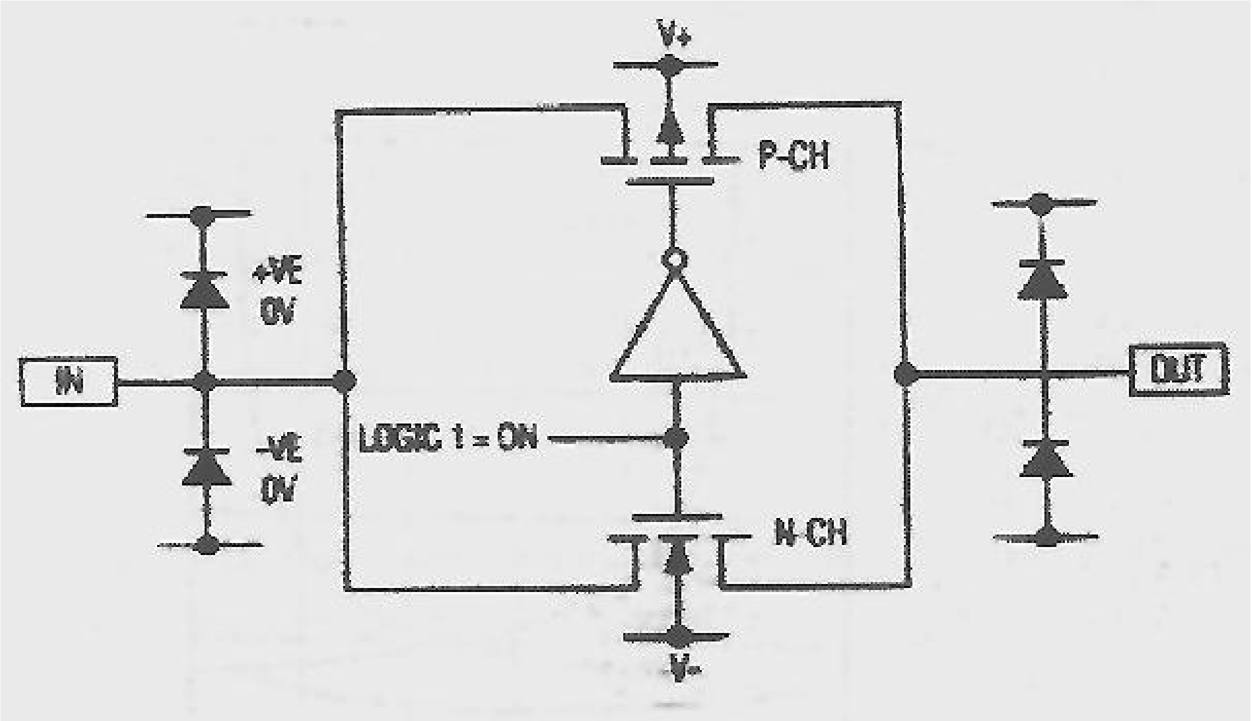


FIGURE 3. PARASITIC DIODES PROVIDE A PATH FOR FAULT CURRENT WHEN A CONVENTIONAL ANALOG SWITCH IS EXPOSED TO OVERVOLTAGE

56 Somewhat lower levels of current (below that of overheating and damage) can still cause latch up in the multiplexer.

57 And once it crosses a diode junction, the fault current becomes a flow of injected minority carriers that "spray" into the SILICON substrate.

58 Collected by other switching devices, this current can induce an error voltage in every channel.

59 Turning on parasitic diode clamps the multiplexer output to one supply rail - an action that can damage external circuits connected to that output.

60 The cause of damage may not be obvious, but an output transient (to the rail) caused by momentary over voltage at the multiplexer can destroy an A/D converter's input, or cause differential overload and long settling times in an op amp.

61 Several design measures offer protection for a CMOS multiplexer and its associated external circuits.

62 These measures include connecting a resistor in series with each channel input, connecting diode-resistor networks to control the fault effects, and choosing a multiplexer whose architecture and process technology provide fault-tolerant properties.

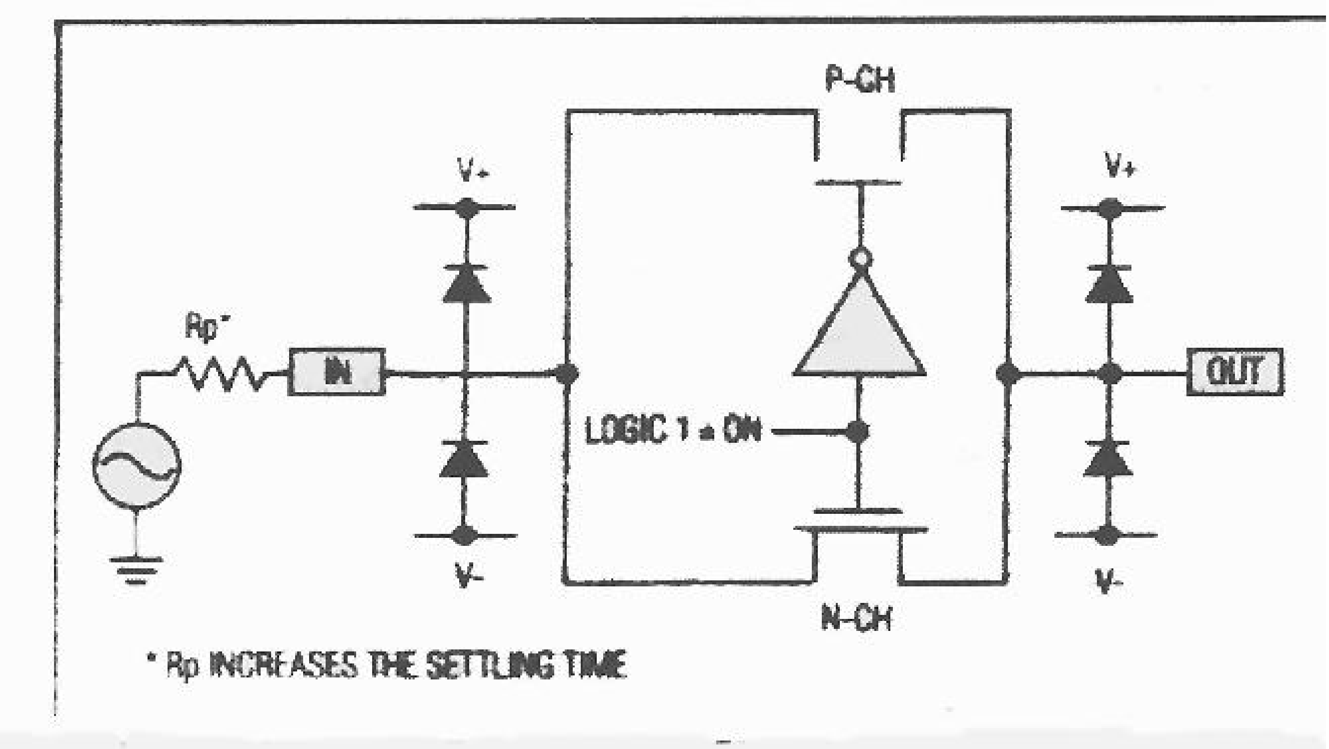

FIGURE 4. Adding a series resistor to the switch of figure 4 limits fault current, But it also adds to the switch resistance and lengthens settling time

63 The simplest form of protection adds series resistors that work in conjunction with the internal protection diodes (Figure 4)

64 The resistor values are critical because they present a trade-off: larger values give more protection but introduce greater signal errors.

65 Leakage current into the multiplexer also flows through the series resistors, causing an error voltage that worsens with temperature (the leakage doubles for each 8°C increase above ambient).

66 Lowering the resistor values can reduce error to an acceptable level, but the lower value may allow too much diode current, threatening latch-up in the multiplexer.

67 As a rule, unless otherwise specified in the data sheet section on absolute maximum ratings, you should limit the diode current to 20 mA continuous or 40 mA peaks.

68 Low leakage currents can offset this drawback of large protection resistors.

69 New, ultra-low-leakage multiplexers such as (MAX328 and MAX329) have extended the design limits for series-resistor protection over those for earlier-generation multiplexers.

70 The new devices low leakage (±1 pA at 25°C; ± 20 nA at 125°C) allows very high-valued protection resistors.

71 Resistors of 150 kΩ, for example, admit fault currents of only 1 mA while withstanding ± 150 V input.

72 At ± 1500 V, they admit fault currents of only ± 10 mA.

73 The resistors produce only ± 3 mV of additional error at 125°C.

74 Note that in the next figure at ± 1500 V protection resistors require 15 W ratings for continuous duty.

75 However, in most applications you can scale this thermal rating considerably because the over voltage has a much lower duty cycle.

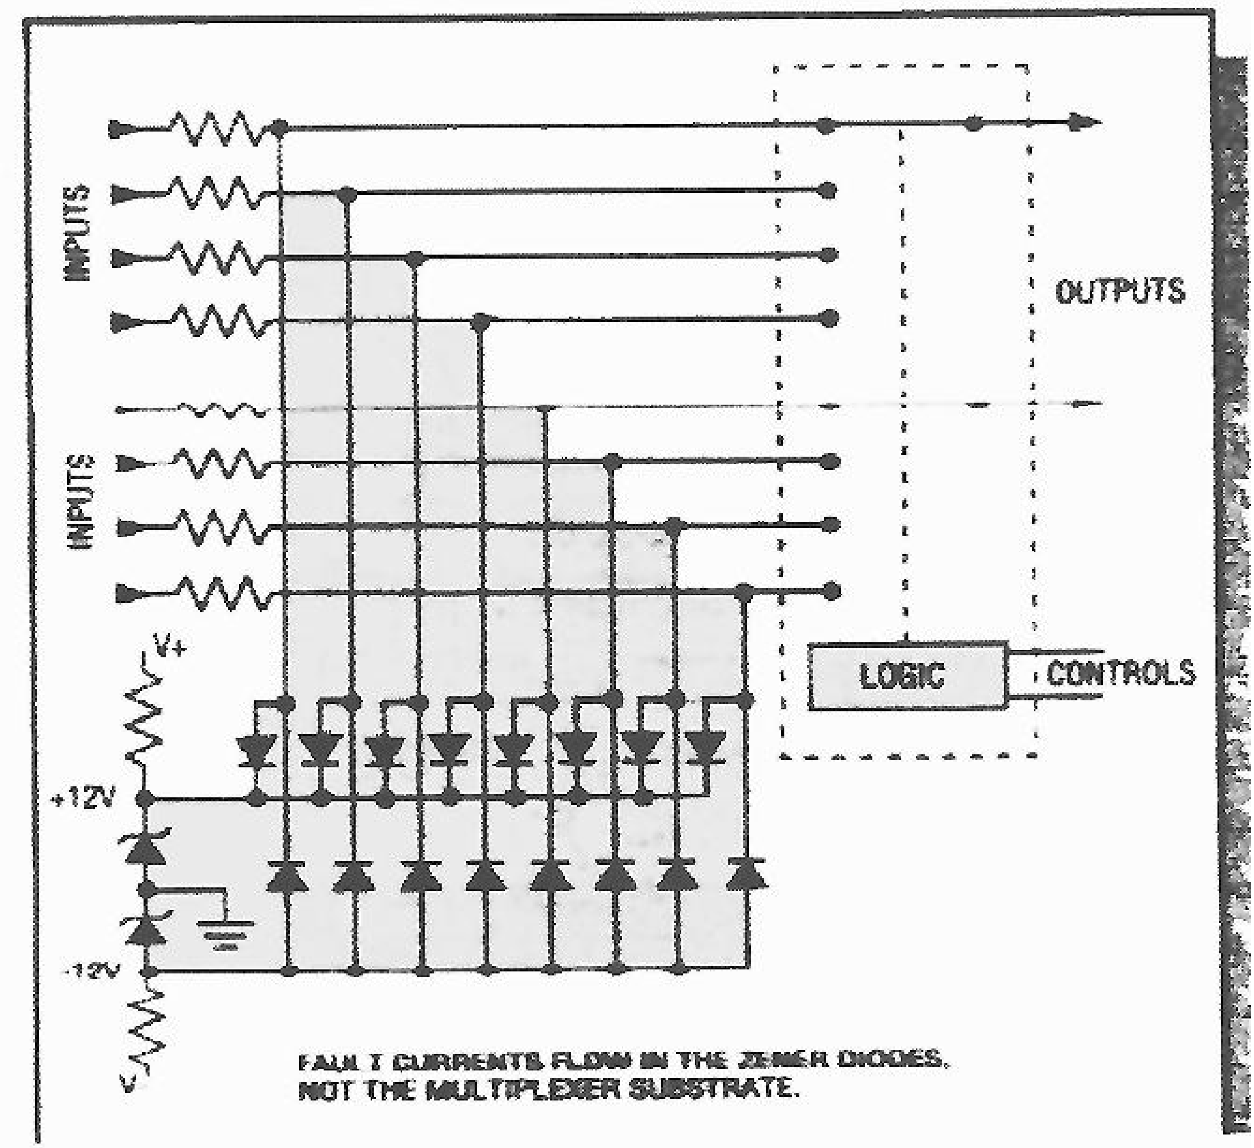
76 External resistors thus offer flexibility - you can choose different resistor values for different channels in the same device, and scale their power ratings as required.

77 Integrated resistors, on the other hand, are constrained by their package power rating; this rating may limit the number of channels that can withstand over voltage at the same time.

78 The series-resistor approach protects the multiplexer, but it does not prevent corruption of signals in the selected channel.

79 These signals are at the mercy of over voltage in any of the unselected channels.

80 But the direct cause isn't overvoltage ; it's fault current (the injected minority carriers mentioned earlier) flowing into the substrate via one or more protection diodes.



INPUTS
INPUTS
OUTPUTS
LOGIC
CONTROLS
V+
+12V
-12V
V-
FAULT CURRENTS FLOW IN THE ZENER DIODES,
NOT THE MULTIPLEXER SUBSTRATE.

FIGURE 5 Fault protections for a conventional multiplexer entails current limiting resistors. Two zener diodes for a bipolar clamp voltage network and dual clamp diodes for each channel.

81 Eliminate that substrate current and you eliminate the gross signal errors.

82 One way to handle the fault current is to divert it into an external network (FIGURE 5 above).

83 Two zener diodes produce ± 12 V clamps levels, centred within the multiplexer's ± 15 V supply rails.

84 Then, instead of flowing through an internal protective diode, the fault current due to over voltage on any channel flows through one of the two external protection diodes for that channel.

85 Though it offers excellent protection, this technique requires a large number of

external components.

86 And, the external diodes produce additional leakage current that precludes use of the high-valued series resistors discussed earlier.

87 The external components represent extra board space, not to mention the cost of purchase, test, through-hole assembly, and inventory.

88 I think that a better solution is to integrate this protection with the multiplexer, on a single chip.

89 Fault-tolerant multiplexer require no external components, yet are capable of withstanding high levels of over voltage without corresponding high levels of fault current.

90 They achieve this protection with an internal design that is quite different from that of conventional multiplexers.

91 Each switch in a fault-tolerant multiplexer is actually a series connection of three MOSFETs, in order n-channel/p-channel/n-channel (FIGURE 6a) below.

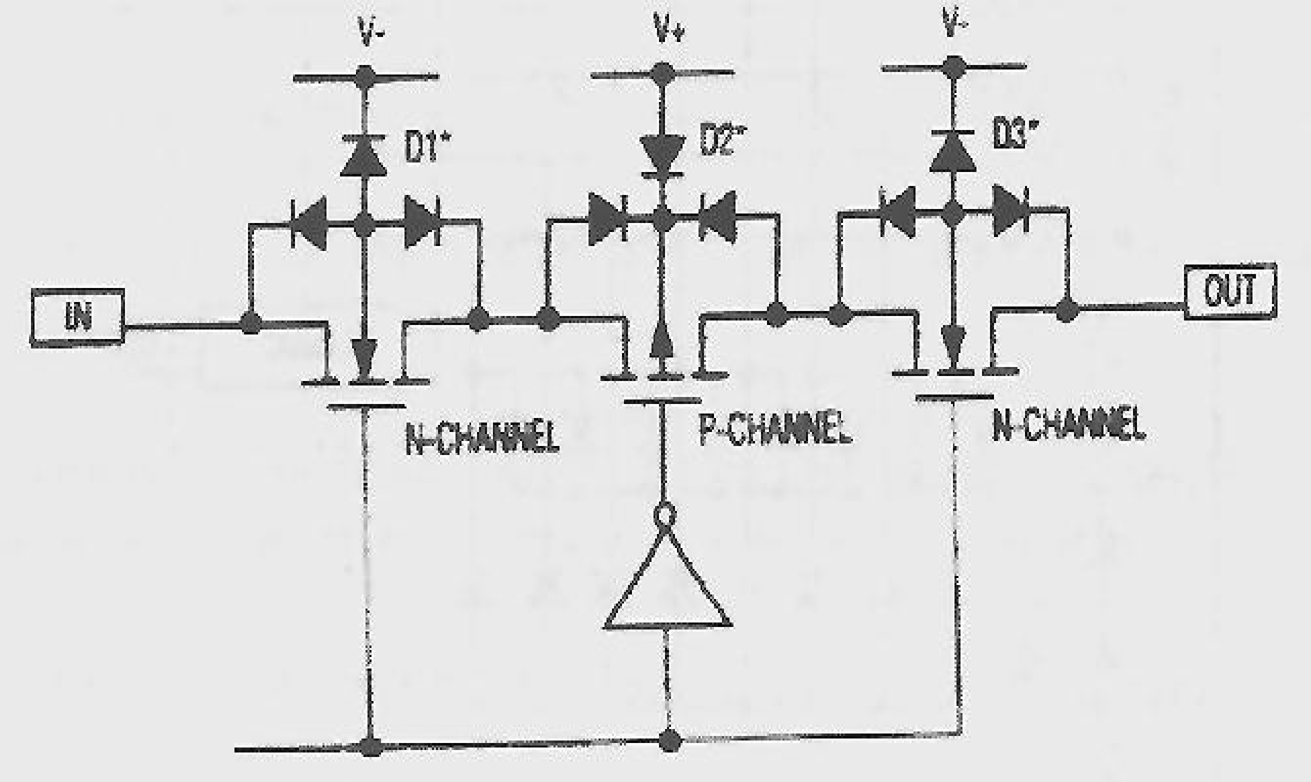


FIGURE 6a. The 3 MOSFET switch element of a fault-tolerant multiplexer

92 Internally generated drive voltages turn the switch on by simultaneously driving the n-channel gates to the positive rail and the p-channel gate to the negative rail.

93 The switch then remains on for as long as the analogue signal (which modulates the gate-source voltages) remains within limits set by the n- and p-channel gate-source thresholds.

94 Typical gate-source thresholds are 1.5 V for n-channel devices and 3 V for p-channel devices.

95 Therefore, with ± 15 V supplies the thresholds confine a multiplexer's input signals to the range - 12 V to 13.5 V.

96 Because one of the three MOSFETs in a switch begins to turn off as the signal exceeds either limit, the switch on-resistance versus input voltage assumes a characteristic "bathtub-shaped" curve FIGURE 6b, below.

97 The resulting high impedance in the off state is very convenient: the switch is off, blocking the over voltage, and fault current is virtually zeroed.

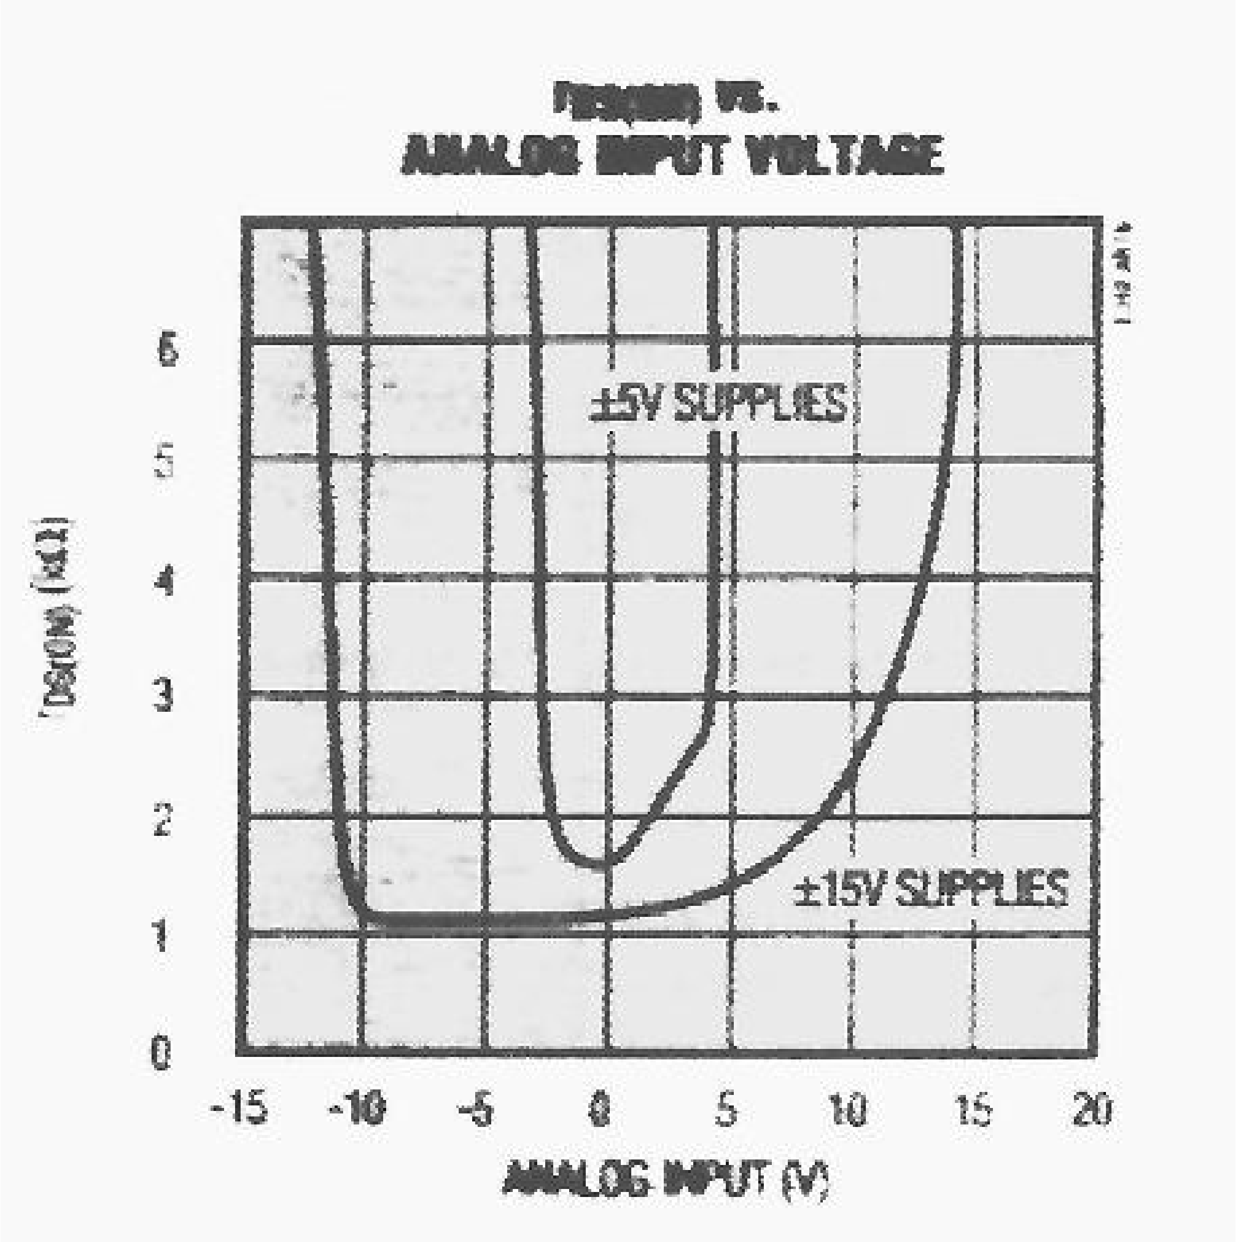

FIGURE 6B. **Has an on resistance characteristic shaped like a bathtub.**

COMPONENTS FOR EVALUATION 1993.

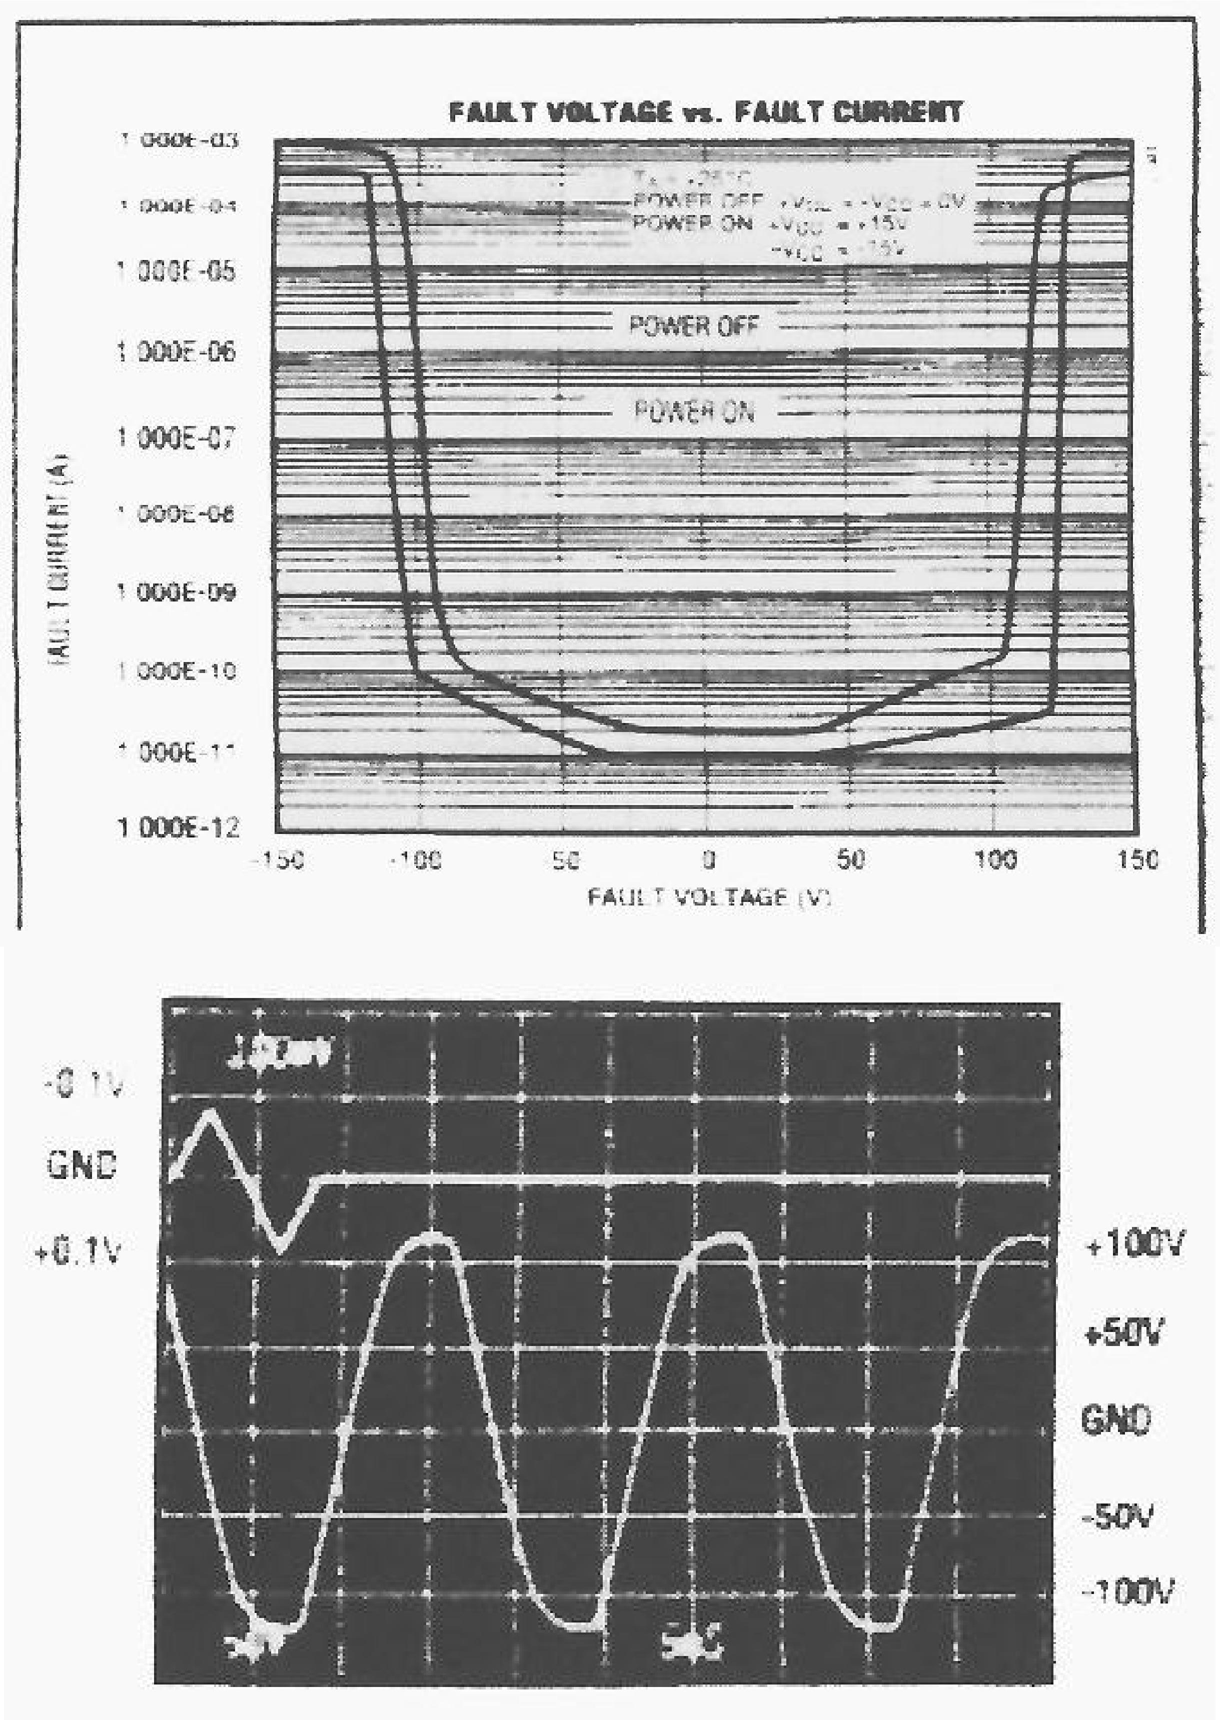

FIGURE 7. Report on next page.

COMPONENTS FOR EVALUATION 1993.

FIGURE 7. The onset of avalanche (fault) current in a MAX388 multiplexer defines a Fault-tolerant region of approximately ± 100 V.

A 0 V signal in the selected channel (top trace) is unaffected by ± 100 V applied to an off channel.

---

98 Substrate (fault) current flows only as a result of avalanche, which occurs when the over voltage exceeds a limit, set by the MOSFET's geometry and doping levels.

99 Below the avalanche limit, signals in the selected channel remain unaffected because the over voltage produces no substrate current

100 The series-connected switch also turns off when power is removed.

101 This behaviour simplifies the design of redundant systems; because multiplexers connect to common signal lines can be powered down without loading the lines.

102 Dr. Edwards please note that all these wonderful things quoted here were conceived in the world of fantasy, but their birth was delivered in the world of reality.

103 Yes Dr. Edwards I am here to teach you as well as every one else, so please listen very careful to what I state, and take note.

104 To my knowledge, Maxim offers several series-structure multiplexers.

105 The MAX358 and MAX359 devices (1-of-8 and dual 1-of-4) withstand over voltages to ± 35 V, and the MAX378 and MAX379 are similar devices that withstand over voltages to ± 75 V.

106 MAX368 and MAX369 add latched address inputs to the basic 35 V tolerant models, and the new MAX388 and MAX389 are latched models that withstand ± 100 V.

107 The non-latched devices are pin compatible with industry-standard multiplexers DG508/509: the latched devices are pin compatible with the latched models DG528/529.

108 As shown earlier in FIGURE 5, conventional multiplexers such as the DG508/509 require numerous external components to duplicate the fault-tolerant capabilities mentioned in this report.

109 MAX3XX devices not only save the cost and board area associated with external components, they offer capabilities not available in discrete-component circuits.

110 MAX3XX devices always turn off when over voltage is applied, but the switches of FIGURE 5, remain on in the presence of over voltage whether power is applied or not; this is only a tiny part of my thinking process for this development work.

I never knock NASA product, in effort to push mine - that is not cricket!

COMPONENTS FOR EVALUATION 1993.

111 The following (TABLE 1) shows the cost advantages of fault-tolerant multiplexers vs. the non-protected DG508/509 alternatives.

TABLE 1. NONLATCHED MULTIPLEXERS

	DG528/ DG529	MAX368/ MAX369	MAX388/ MAX389
Inherent O/V protection	NONE	± 35 V	± 100 V
Resale cost, 1 K pcs	$1.78	$3.25	$3.75
External component cost And assembly	$2.15*	0.00	0.00
TOTAL SYSTEM COST	$3.93	$3.25	$3.75

* = 28 External components (x) .03 (+) 28 (x) 2 leads (x) .007

The cost of the:

(1) 10 resistors

(2) 16 diodes

(3) 2 zeners

112 In FIGURE 5, is about $0.92, based on the purchases of 1 K pieces or more.

113 Plated-through holes are about $0.007 each, and the assembly cost for axial-leaded parts is about $0.03 per component.

114 The resulting total for multi-component protection exceeds that of the simpler, single IC protection offered by Maxim.

115 External components also require five times more board area than the IC alone.

116 The cost in FIGURE 5's, circuit is even greater if you consider the cost of troubleshooting, reliability effects, and other hidden expenses.

117 All of TABLE 1's ICs have an Absolute Maximum rating of 44 V between the V+ and V- terminals, but increasing die sizes from left to right necessarily escalate the 1 K-pc prices.

118 I had to leave out what would have been FIGURE 2, as part of it was far too large to include there. I have now reduced its size to half; it means that the contents do not stand out as clear as planned.

119 I hope that you will obtain enough **FACTS** from it to understand what it shows.

LECTURER : *John Roy Robert Searl.*
STATUS : *Head of R&D Human Studies.*

Star Ship Ezekiel MK V agreed concept:

Should be based upon my dreams one and two contents, that is to use the law of the squares in the concept design.

First, let us look at the squares, what are we talking about in reality?

8	30	34	3	5	31
35	1	28	9	26	12
18	17	15	21	27	13

122	52	67	112	177	7
27	157	17	162	32	142

You should see that I am using square six; you can also see that it is constructed from 36 cells, each cell holds a value.

I use square six for flight requirements, why do I use square six and not some other form of mathematics.

Son that is a good question, you see I have no knowledge on mathematics, as I had no formal education, like you because I have no normal hearing.

It was impossible for me to understand what my teacher was saying, I did nether the less understood what her hand was saying to my checks of my bum that she was going to make it red and hot – and she did to that issue there is no argument.

They fail to try to find out why a child cannot learn, do not question if they are deaf – they assume they hear.

Have selected the square that you are going to employ you then have to select the elements, which is important issue that the dream one say go square four, which is absolutely correct but only for land base use, unfortunate not powerful enough for flight work. Looking at dream one, I cannot help seeing that always there are eight squares, not only that I am always in square 2.

This is where you actually use your brain, ***WHY***?

Because that is what it is actually for, to be used, and I had no option but to use mine, that is why I conceived the Searl Effect concept.

Here was a dream, which kept re-occurring surely, there must be some logic reason for it. Now if we take two away from eight we get six, you agree, strange that dream run for six years.

That two covers many issues that are actually involved, I shall be involved in two completely different fields of technology:

1. ***Land base energy requirements.***
2. ***Flight base requirements.***

That dream also stating that you have to use four layers, three of which must be true elements plus one, which is not a true element but a molecule structure.

A concept is being born, and it is from such a chart, which as displayed at the heading of this document that I used within this technology.

Now I am standing in square two: there are two states involved here up and return back, thus I accept that I shall be involved in two different domains.

One, which is down representing ground systems; and other one up; representing flight. Thus cell two and cell four plus cell eight are the key issues as cell three you have to hop over and not into it.

I multiply these together and obtain:

2 x 4 = 8   8 x 8 = 64

Therefore, eight must have some importance, and likewise 64 – this is where my brain does the thinking and not me.

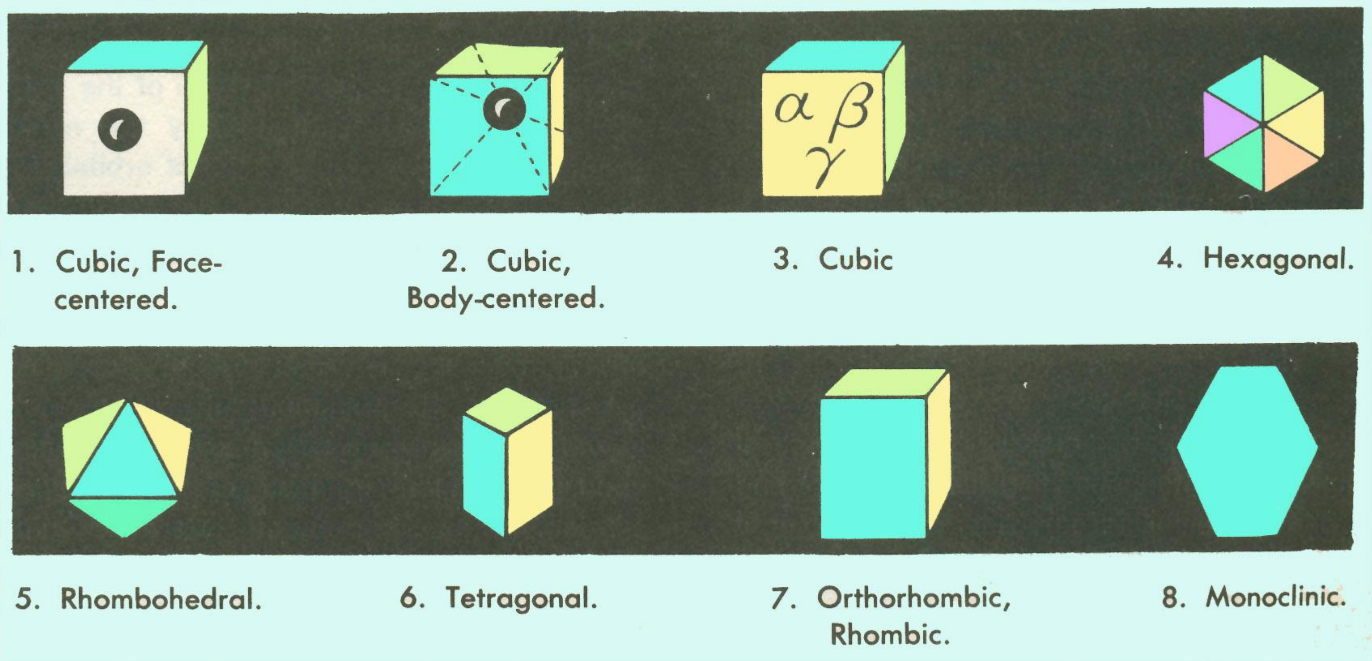
You can guess that eight relates to the periodic table, the 64 relates to the flight side, just for this moment I shall concentrate upon that issue eight.
It relates to the electrons, which I have already explained within this book the behaviour of the atom in its construct of the electrons.
That the four layers move from the outside layer the density goes up as you go towards the centre, except for the molecule layer, which controls the flow of electrons from the rare earth material.
Slowly a concept for research and study is in the development state
With all new idea, it is a case of probing in the dark until some light appears, as it will do if you probe deep enough, as I had to do.
At first, it looks impossible and often it is only a small issue to be corrected then its all go.

Dream one state there are two prime states in the universe.

1. ***Positive and negative***
2. ***Electrons and positrons***
3. ***Magnetic north and magnetic south***
4. ***Stationary plates and moving parts the roller s***
5. ***Conductors and insulators***
6. ***Superconductivity and non superconductivity***
7. ***Yes and no***
8. ***Left and right***
9. ***Hot and cold***
10. ***Particle and wave***
11. ***Male and female***
12. ***Current and magnetism***

Prof. John R.R. Searl
Inventor
of the 21. Century

These are all important issues, because they are all part of reality, and my world is reality without question.



1. Cubic, Face-centered.
2. Cubic, Body-centered.
3. Cubic
4. Hexagonal.
5. Rhombohedral.
6. Tetragonal.
7. Orthorhombic, Rhombic.
8. Monoclinic.

Here are eight conventional diagrams of crystals forms.

Which is strange that this hopscotch patch had its system based on eight squares, in the following manner; from bottom to top?

Squares one, two and three in a vertical line then square four and five in horizontal mode followed by square six in the vertical mode ending with square seven and eight in the horizontal mode.

Square one is outside of the function as it represents that level one of all squares structures is its DNA upon which that square system is constructed.

Squares are no different to all the animals; a DNA system controls the construction upon how each species or square created by.

Maybe I have given you a bit too much to digest, after all it is my world born into it and have lived it all my life, therefore, to me it is easy for me to follow, as a yellow brick road would be.

It is an old saying when they is something unknown to be explain it is wiser to give it in small bite at a time so that it may be digested slowly by those who wish to learn and understand, agree most people can learn the problem remains will they understand that which they have learnt.

This is my world of reality, the world of tomorrow's technology, the ***Gyro-Flywheel-High Energy Density-Mechanical-magnetic device*** the ***Searl Effect Generator (S.E.G)*** and the ***Inverse-Gravity-Vehicle (I.G.V),*** you might not yet got it, but you should had done so, except for evil minds whose ignorance and greed have blocked you from having it. Unfortunate there is no more dangerous combination than those who steal in ignorance for personal gain

TABLE 1:

Electronic Properties of individual Atoms:

Columns 1 and 10 contain the atom number Z, equal to the number of elementary positive charges borne by the nucleus and also to the number of extra-nuclear electrons in the neutral atom.

Column 2 contains the name of the element or atom.

Column 3 contains the symbol for the element or atom.

Column 4 contains the atomic diameter as an expectation value from quantum mechanical average-energy-of-configuration Hartree-Fock computations for free atoms – atomic data 4, the unit is 10^{-10}m.

=0.0000000001 m WOW!

What do you think about that Flowerbower?

You poor creature of misfortune: that is beyond your brain capabilities to understand because that is reality.

Column5 contains the ionization potential in volts:
The ionization energy is the ionization potential multiplied by the elementary charge e, and has the same numerical value as the ionization potential when the latter is expressed in volts and the former in electron volts:

(1 eV≅ 1.60219 x 10^{-19} J)

That is: 1.60219 x 0.0000000000000000001 J

How are you coping Flowebower, guess there is a great amount of hot air rushing out of that rear end of yours practice makes perfect ready for YouTube attack again?
I feel that I should halt here to let you recover from this reading, as there is such a lot to show what I knew so long ago now.

Though I cannot no longer study at the same rate due to lack of hard cash not being available, at least I try to continue to learn about reality, which also includes you.

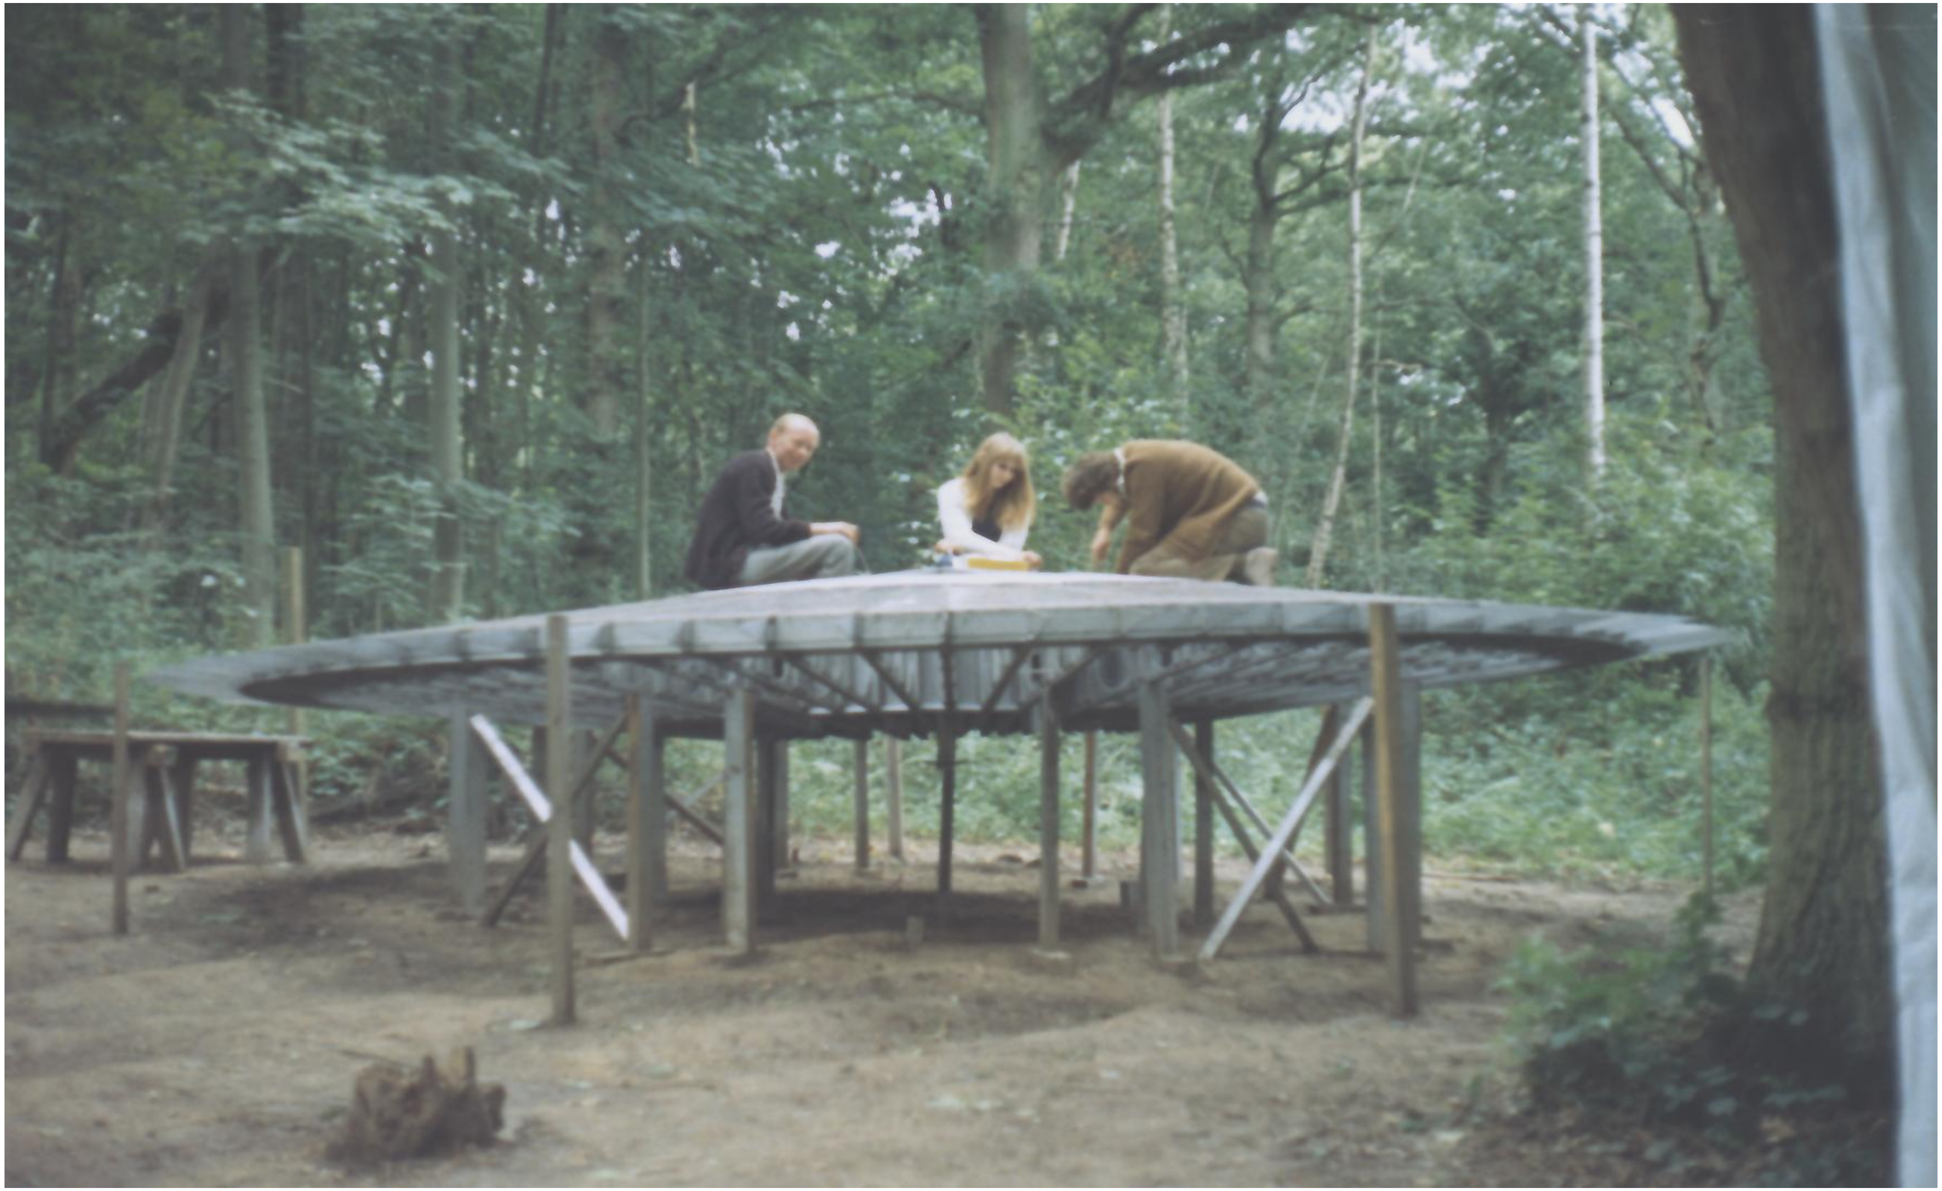
Prof. J. R. R. Searl Head of research and development.
Manned Flight – human studies.

Electric Express Locomotive, modelled on the class BB10000 of the Société Nationale des Chemins de Ferrancais (SNCF, or French National Railways Co.)
Finished in green
This was one of a hundred different trains that I used to display on special show days which were stolen while I was on Business in Canada by my family and replace to be stolen again by then while I was away.
They sold them for next to nothing in cash.

Cost me £8.00 plus postage and package.

IMPOSSIBLE MADE POSSIBLE BY A FOOL NAMED SEARL AND GROUP 1968.



MY MEDICAL KNOWLEDGE 1993.

JANUARY 1993

1 **STARSHIP EZEKIEL MK.V**. is designed to have its own hospital, and this also apply to a housing complex upon that design.

2 But in 1968, its equipment design was very bulky and heavy, so now 25 years later, what is new that can be use to reduce both the size and weight of that equipment which is needed.

3 There is a subject matter upon the human body which is really never spoken about, yet to many it is a hell of a problem, one which I must make allowances for in the design of **STARSHIP EZEKIEL MK.V**. or even a housing complex upon the same structural concept.

4 The subject again is sensors, but in this case it is a chemical fibre sensor, which is the subject of this discussion.

5 This discussion is based upon a subject matter which one do not talk about at the dinner table, yet it is involved with your dinner one way or another.

6 It is a new optical sensor for monitoring bile in the stomach which is not just more accurate than existing techniques, it also works around the clock with little disruption to the patient's daily life.

7 Which of cause is great stuff for all of us who suffer from any bile related problems.

8 Chemical sensors based on optical fibres are advancing faster in biomedicine than those, which depend on competing technologies.

9 And fibre-based chemical sensors are developing more rapidly in biomedicine than in any other field.

BILITEC 2000
mark

THE COMPLETE BILE SENSOR, WHICH MONITORS BILIRUBIN.

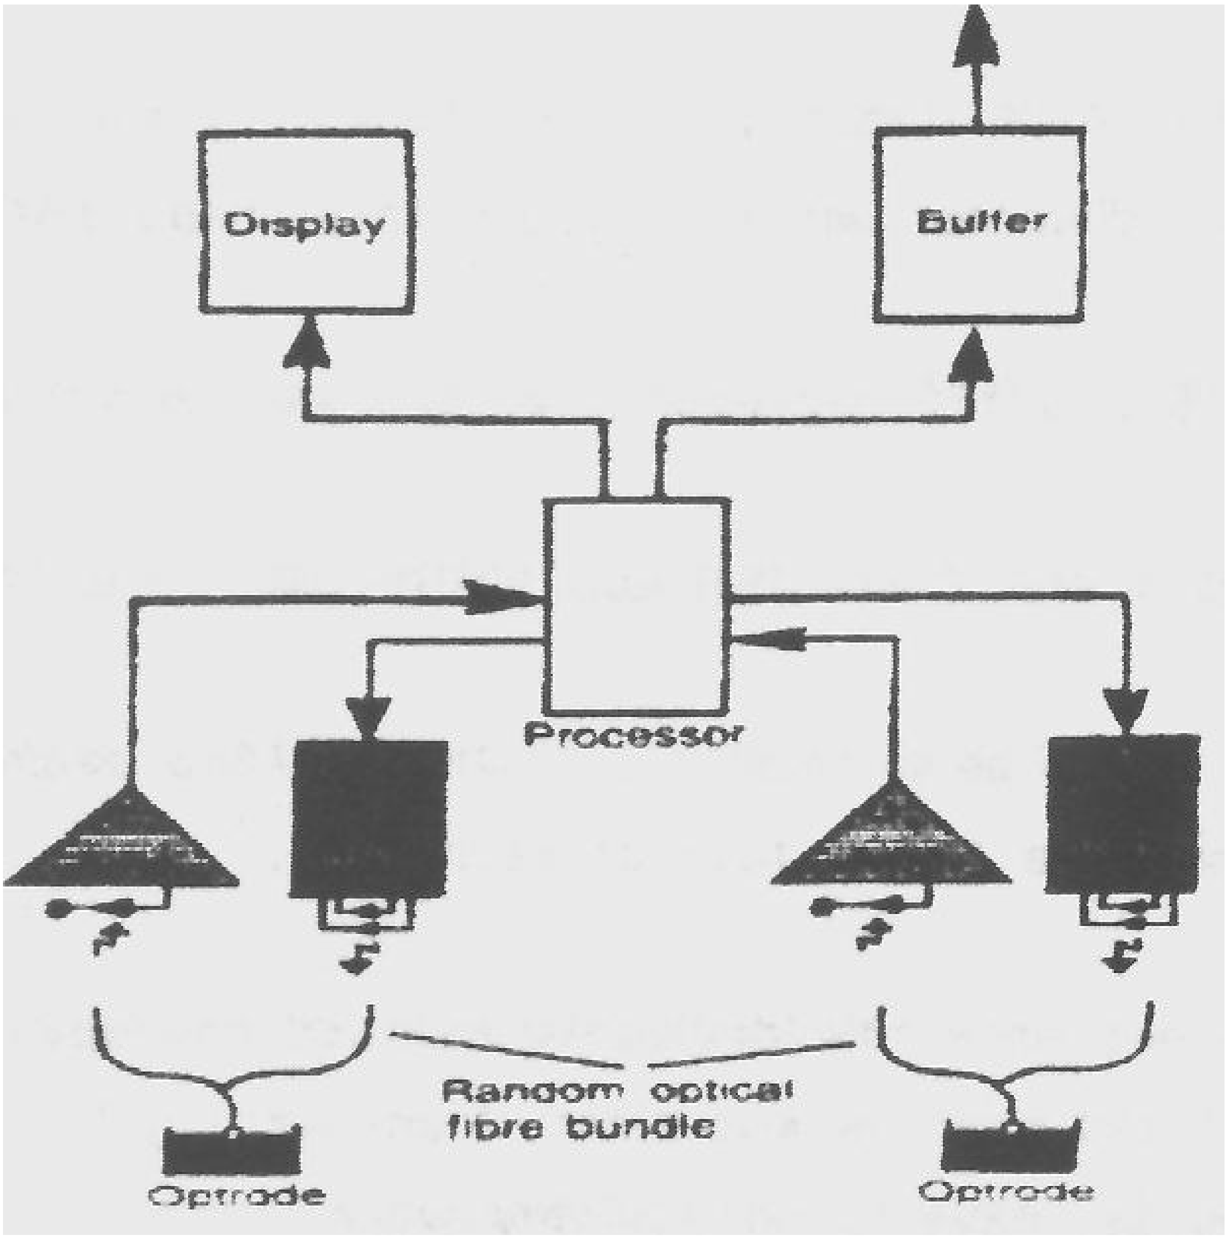


FIGURE 1b. IT'S OPTOELECTRONIC SYSTEM.

10 I regret that these last two pictures are missing, and I have had to scan them from book 4, which was a photocopy of a photocopy, so as to maintain the same data.

11 Wherever I can I have replaced those pictures or drawings with new ones, but some take too long to re-draw them.

12 But I hope that it will give some indication of what I am talking about.

13 Some scientists might disagree with these two claims which were made by Francesco Baldini, who researches chemical sensors at the Istituto di Ricerca sulle Onde Elettromagnetiche (IROE), Florence, Italy.

14 Yes Mr. Anders Heerfordt, Dr. Edwards and Gunnar Sandberg, I bet that none of

you knew that I know about that place or that person.

15 I also bet that you did not know that I knew the following **FACT** that an IROE sensor, which continuously monitors bile in the oesophagus (for those who do not know what oesophagus refers to, don't worry I am here to tell you, its the canal which extends from the pharynx to the stomach.

16 To my knowledge it is about nine inches long, at least that is what I understood back there in 1950.

17 You are happy now that you know what I am talking about; you are not, why?

18 You are confused as to what the term pharynx relate, o don't worry, I am here to tell you. It’s the muscular pouch lined with mucous membrane situated at the back of the mouth.

19 It leads into the oesophagus, and also communicates with the nose through the posterior nares, with the ears through the Eustachian tubes, and with the larynx.

20 Now you are happy?

21 You are not, you don't understand the terms used, well I am sorry I have to leave that for another book, or otherwise the subject of this discussion will never appear within this book.

22 This sensor functions by an optical fibre probe inserted through the patient's nose, has just gone on sale.

23 At this moment in time, I do not know what it cost.

24 Data from the optical transducer or optrode on the end of the fibre are collected in a small battery-powered unit, which is light enough to hang off the patient's belt.

25 The sensor takes readings every 4, 8 or 16 seconds, which it displays or records for analysis.

26 Buttons on the unit allow the patient to record pain, meals and periods of rest.

27 The Italian researchers have just started laboratory tests of a similar sensor to monitor acidity levels in the stomach.

28 They are also working on prototypes of fibre sensors that measure the pH of blood, oxygen levels in liquid or gas streams, and others, which, in combination with enzyme reagents, could analyse biological compounds.

29 By now you should all know that I am determined to see that every functional unit within the concept of **STARSHIP EZEKIEL MK.V**. or in any similar housing compound will be of the absolute accurate and fast technology that science can offer.

Well you so-call experts what a disgrace you are to your profession with your insults of crap.

30 Baldini told the Biomedical Optics conference in Hungary that fibre sensors are succeeding in biomedicine because they lack electrical contacts, they are tiny and they come in virtually any shape.

31 These qualities, which I appreciate, added to fibre's inherent safety, make the technology "competitive with traditional sensors in both chemical diagnostics and multi-test kits and allow, in some cases, performances which are unique."

32 As I stated in 1968, that biomedicine's requirements on **STARSHIP EZEKIEL MK.V**. demand for quality and safety drives innovation by forcing designers to think carefully and to base their sensors on a "thorough spectrophotometric investigation".

33 As I stated in 1968, spectrophotometry leads to a "better understanding of chromophores, immobilised or not, which act as an optical transducer and optimise the optrode's optical performance", and this is also what Baldini stated.

34 "If the goal of the sensor is in vivo measurements, then particular attention must be paid to the biocompatibility of the optrode."

35 There are three basic elements to each sensor :

(1) An optoelectronic system

(2) An optical fibre

(3) An optrode on the end of the fibre

36 Some optrodes carry chromophores, substances that have unique absorption spectra in the presence of specific chemicals.

37 Other optrodes depend on the absorption spectra of target chemicals such as bilirubin, which has an absorption peak at 452 nm.

38 Bilirubin is the main pigment in bile, which can cause disease if it enters the stomach from the duodenum.

39 You look confused at a much higher level, let me deconfuse you, Duodenum (du-o-de'-num) the first nine or ten inches of the small intestine, from the pyloric opening of the stomach to the jejunum.

40 The pancreatic and common bile ducts open into it.

41 Now you are happy, you are not, sorry, I must continue with my discussion, or otherwise I will never get it done.

42 A typical sensor has two identical fibre channels to monitor a pair of sites simultaneously.

43 Two diodes in each channel couple a reference wavelength and a signal

Wavelength (matched to the target chemical or the chromophore in the optrode) into one arm of a forked fibre.

44 The forked probe is a randomly mixed bundle of polymer optical fibres in a biocompatible black polyurethane catheter.

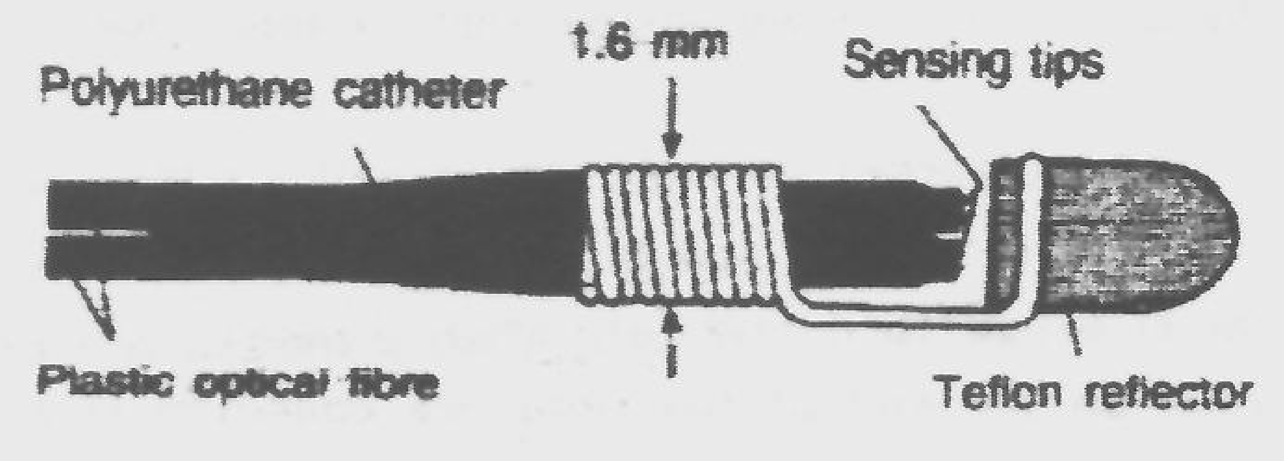

FIGURE 2. Open optrode for pH measurements with bromophenol blue

45 Light from the two sources passes to the optrode and then reflects back along the fibre and out of the second arm onto a photodetector, an amplifier and a processor.

46 The processor drives the two light sources and passes collected data to an internal buffer for transfer to an external computer.

47 Baldini has developed several designs for optrodes.

48 One is based on chromophores immobilised on glass microspheres in a stainless steel tube, which has perforations or slits in its wall.

49 Each of these "windows" is smaller than the spheres but large enough to allow liquids to enter.

50 An early optrode to measure acidity levels in the stomach was based on a tube 15 mm long by 0.8 mm in diameter, perforated with 70 µm holes and containing a thymol blue chromophore immobilised on glass.

51 Test measurements show that the prototype is sensitive to 0.007 pH to 4 pH, but the response time of several minutes is too long, for my requirements for **STARSHIP EZEKIEL MK.V**. Programme.

52 A narrower tube containing more holes would improve response times but the viscosity of gastric juices in vivo would reduce them again.

53 Although the perforated optrode was abandoned as a gastric monitor, a modified design with slits instead of holes measures the acidity of blood to 0.02 pH from 6.8 to 8 pH, with response times of about one minute for each 0.25 pH step.

54 Well that is getting better.

55 However, can we improve on that timing period?

56 The chromophore is phenol red immobilised on polymer spheres and the sensor's sources emit at 570 nm for the signal and 660 nm for the reference.

57 Tubular optrodes are compact and simple.

58 They also suffer from slow leakage of the phenal red and, unless degassed, air bubbles reduce their typical response time of 30 seconds.

59 IROE has decided, therefore, that the design of the optrode is not suited to in vivo monitoring of acidity levels in blood.

60 Another optrode, designed to detect OXYGEN, is based on an organic metallic compound adsorbed onto a plate.

61 Such compounds, bis (histidinato) cobalt (II) in this case, change their absorbency spectra in the presence of OXYGEN.

62 A layer of SILICONE protects the compound, which is fixed to one wall of a flow cell.

63 The SILICONE allows the compound to react with liquids while protecting it from physical damage.

64 The 470 nm signal and 620 nm reference beams shine through a quartz window in the aluminium cell and reflect off the compound.

65 The optrode is accurate to 0.3 vol. percentage in the first 0 to 10-vol. percentage of OXYGEN in an OXYGEN -ARGON mixture.

66 In addition, is slightly less accurate at higher concentrations of OXYGEN.

67 Response time is about two minutes, depending on the thickness of the SILICONE layer.

68 One of IROE's most promising optrode designs exposes bare ends, or chromophore-carrying spheres fixed on the ends of fibres, to fluids such as gastric juices.

69 This open optrode design was used for the bile sensor, which has just gone on sale, and a version of the design is under test as an acid sensor.

70 At the end of a 500 µm diameter polymer fibre is placed against a heated layer of glass microspheres, the polymer softens and up to 50 spheres carrying about 5 Ng of chromophore penetrate the tip.

71 When the polymer cools, it hardens and fixes the spheres in place.

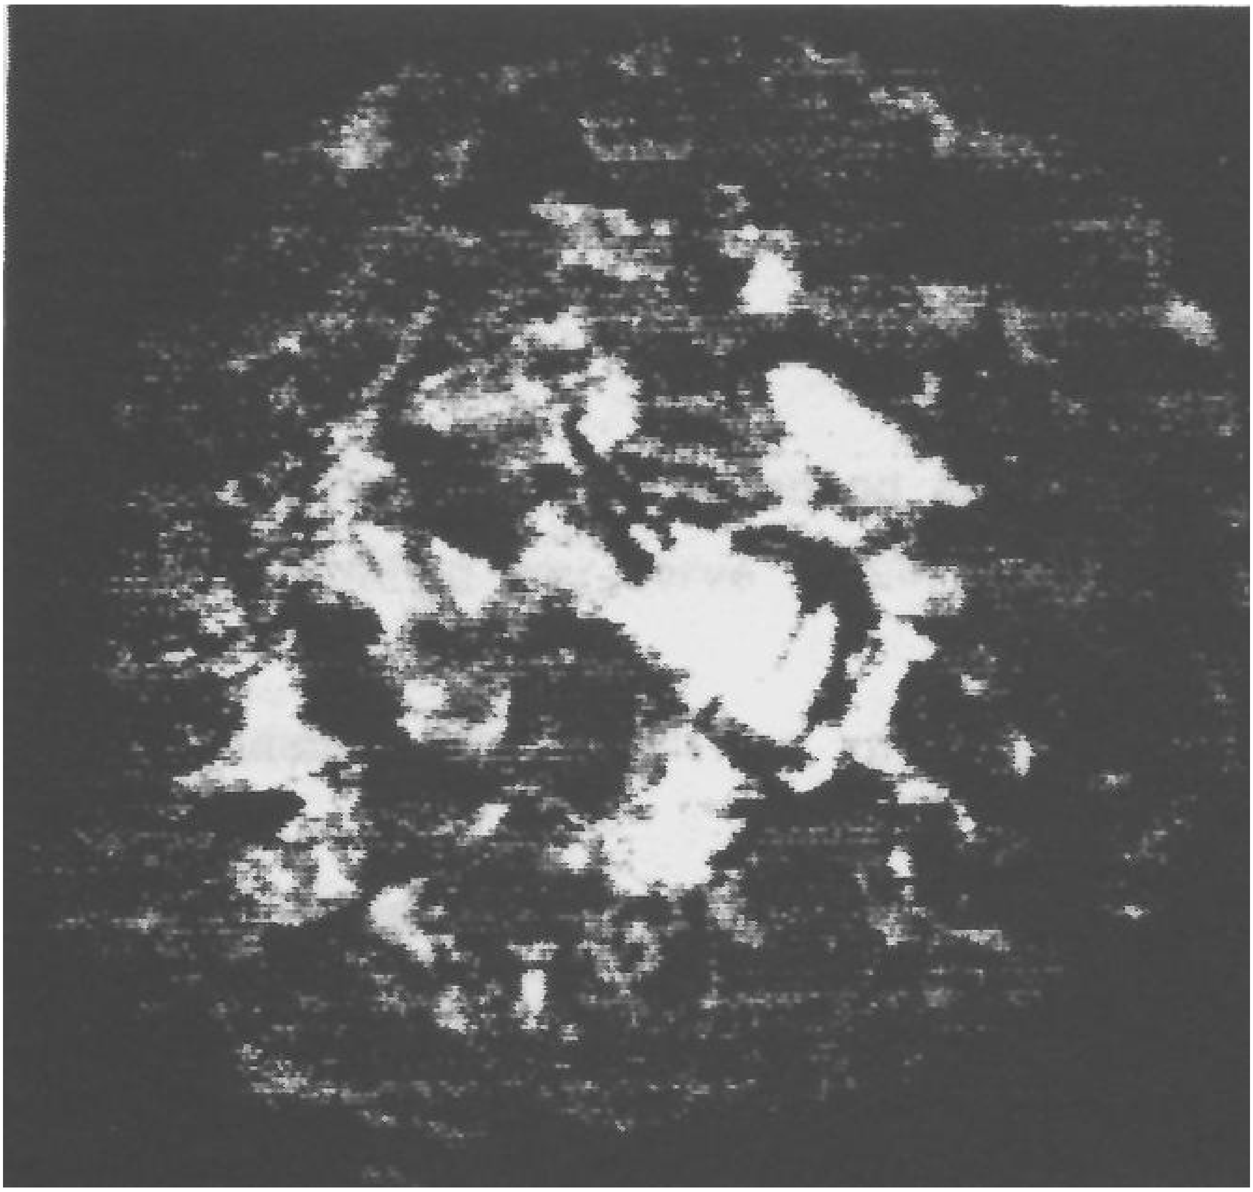

FIGURE 3. Glass spheres carrying a chromophore fixed to a 500 µm Diameter polymer optical fibre.

72 A Teflon reflector mounted by a wire in front of the bare or bead-carrying fibre tips improves the coupling of the signal and reference beams to create an optrode, which is open to gastric juices.

73 Its open structure allows liquids in the stomach to remove contaminants, such as mucus collected by the optrode as it is inserted through the nose and oesophagus, and so ensures a fast response from the sensor.

74 Measurements in vitro proved that an open optrode with bare fibre tips detects bilirubin to an accuracy of four µmol compared with the 0 to 100 µmol range expected in the stomach.

75 Francesco Baldini reports that, based on over 100 in vivo measurements, bare fibre tips are better than conventional medical techniques for detecting bile.

76 For example, the sensor can determine the moment when bile enters the stomach from the duodenum in conditions where conventional measurements do not even detect a change in acidity.

77 Other techniques, such as the injection of a radioactive marker, which is rapidly eliminated by the liver and bile ducts, record the presence of bile in the stomach.

78 However, radioactive markers, unlike the new sensor, cannot give information about the concentration of bile.

79 An open optrode, with spheres carrying bromophenol blue fixed to its fibre tips, has just begun in vivo trials to monitor acid levels inside the stomachs of patients.

80 The trials are in collaboration with Prof. Paolo Bechi of Clinica Chirurgica III at the University of Florence.

81 Two sources shine 595-nm signal and 870 nm reference beams down its 0.5-mm diameter fibres.

82 So far, the in vitro trials show that the optrode is accurate to ó0.05 pH in the range of 3 to 7 pH, with a response time of a few seconds.

83 Now we are talking my kind of language that is more like what I wish to hear.

84 Baldini reports that hysteresis is greater in acid detection with the open designs than with the perforated stainless steel tube optrode.

85 "At the moment we can't give a sure interpretation of this because the only difference is the thickness of the beads," he says.

86 However, the effect of hysteresis with the open optrode is consistent enough to be removed by software.

87 The other good news about new acidity sensor is that its sensitivity is not affected by temperature and it can be stored in dry conditions for long periods.

88 Baldini now predicts the device will join the bile sensor on the market in about 18 months. I will be watching out for it.

89 This is only one subject matter where sensors will play a vital part of the **STARSHIP EZEKIEL MK.V. PROJECT**, other sensors will be discussed within these books.

90 I will change this point to another point, which often appears.

91 QUESTION

Over the last two years, I have noticed that my penis becomes curved when I get an erection, I have seen my doctor, who has diagnosed **PEYRONIE'S DISEASE**.

MY MEDICAL KNOWLEDGE 1993.

I am 22 and a virgin - and about to go away with my girlfriend, with whom I have a very caring and deep relationship.

I am sure that we will make love and I am worried that I will not be able to manage it.

Can you give me any advice?

92 ANSWER

My first piece of advice is not to worry.

PEYRONIE'S DISEASE, named after a French surgeon, is caused by harmless hard tissue, which pulls the penis to one side or another when you get an erection.

It rarely affects your ability to make love and is best forgotten about - unless it is painful or causes severe deformity, in which case your GP may want to refer you to a specialist.

I can tell you from actual experience that the pain can be beyond a limit, which would allow you to even think of trying to make love.

However, it was not **PEYRONIE'S DISEASE**, which was the cause of my problem; it was the lack of lovemaking.

Not all men have straight penises when erect.

I have seen some unusual sights in my career, one case that was a perfect
Cork screw from base to tip, very, few of which ever interfere with
Love making.

I must admit I do not know how the chap above managed, as it would need three times more space to accommodate it.

Indeed some men are proud of their individuality!

Enjoy your holiday.

93 In 1968, Peyronie's disease was unknown to me, so at that time I would not had known of that problem.

94 Strange as it may seem to one, as I reflect upon this matter, that during my training on the hospital ward, I did not know of such problems. Then let us face it, it is not a normal practice for men to erect themselves, just to show the medical staff what they got as a weapon.

95 To some people they may feel that these discussions are not important to the **STARSHIP EZEKIEL MK.V. PROJECT**, but that is where you go wrong.

96 The designer needs every bit of knowledge across the whole of humankind requirements.

7155
BALTIMORE AND OHIO

THE IMPOSSIBLE MADE POSSIBLE BY FOOLS LIKE SEARL.

1 This is but one of the trains Searl operated on his system using the *S.E.G*. Technology

2 An articulated steam locomotive with tender of the Baltimore & Ohio Company, which again shows proof that the impossible can often become possible.

3 It has a wheel arrangement 2-8-8-0; somehow dream one has again popped in to say hello!

4 Projected by the USRA – United States Railway Administration, the loco group ED-5 of the B & O was built between 1919 and 1920 by the Baldwin locomotive company.

5 Well Dr. Edwards I bet you never knew that I knew that, but the question is did you know that?

6 They had the Baker distribution system and were equipped with a Vanderbilt type tender.

7 The B & O used the articulated locos to haul freight trains on the uneven lines of the Cumberland and on the severe ruling gradients of Crandberry, Cheat River, Newburg.

REALITY OR FANTASY 1978.

Searl’s rail system, which became public, shows locos operating on the **S.E.G**. principal.

8 Very powerful motor driving the two articulated motor groups through a longitudinal shaft and pendular transmission with universal joints.

9 Metal frame in spite of its considerable length this model has an exceptional smooth running and could negotiate curves down to 40 CMS. Radius thanks to the two articulated motor groups.

10 This model is extremely detailed and fully operating valve gear system

11 Length of this model was 40 CMS.

12 Of course, I can carry on and on about this train and its history, but the sole purpose of this article is to answer those idiots who claim by their expertise of bullshit that Searl never had anything.

13 You the reader have to make up your mind if Searl did have or not.

14 Was there such a model available, which he could, had brought matching the claims shown here?

15 Searl does not confirm that today it is still possible to buy a copy of this train, as he has been out of action for some time.

16 His sons, either sold at extreme stupid prices, as they had no knowledge of the cost of those engines stole all of his rail system, from the first to the second one.

17 Stupid people who have no common sense use this unfortunate situation to expose how cleaver they are in bullshitting.

18 That is the only reason they are experts.

19 They are sick in the mind, and represent the reason why this planet is in such a mess.

20 No other animal upon this planet does so much damage. This is a fact!

21 This is the man who gives his whole life to study the problems of this planet; his answer is to transfer all Homo sapiens to Mars. Then this planet will be a paradise.

Prof. John Roy Robert Searl Head of R&D Human Studies.
Medical Division.

Common board PSU circuit diagram.

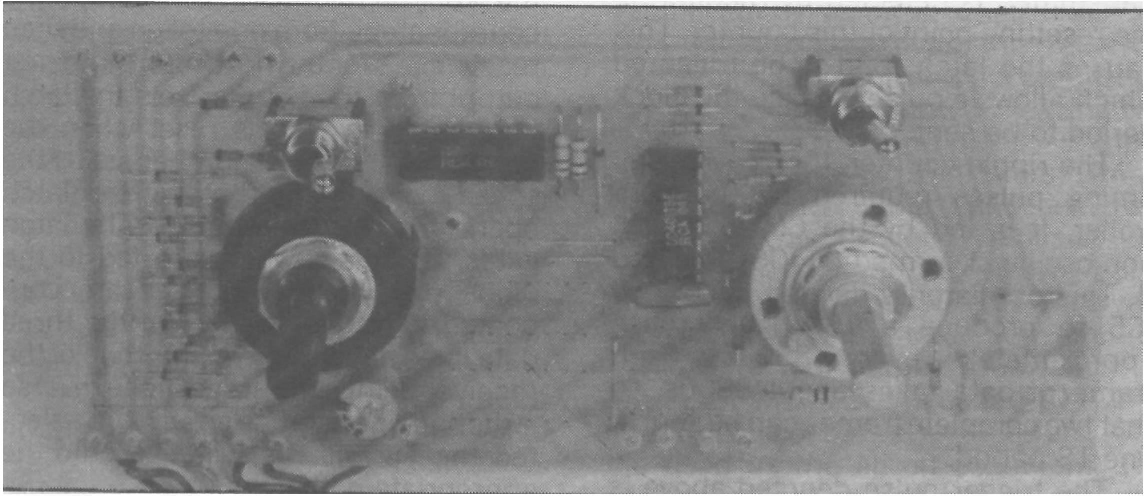
7 If you remember from my past books and newsletters that I wanted, because of the increased number of trains to be able to operate them faster in the effort to demonstrate that you can operate a real system by the same methods.

8 Up till 1968 the trains could be controlled manually, by masses of switches.

9 Unfortunate that did not represent much of a real business by rail.

SEARL'S RAIL CONTROL SYSTEM 1968.

10 Here is the view of the completed control PCB, remember there is not just one off there are many of them.



Completed control PCB, sorry it has not come out very clear.

11 Bear in mind at this time the operation is still controlled by manpower.

12 However, we can now speed up the system; therefore, more trains can operate.

13 As this is a demonstration of a real time business rail system, we shall need to operate far more trains without accident.

14 A model system must be able to perform the same operation requirements as that of a real business system

15 Searl through his model rail system must bring out of the world of fantasy into the world of reality that which sits in his mind.

16 Until he has modelled it, no one can really appreciate what he states possible.

17 Thus in 1968 he has to change much of his rail system, which is rather elementary stuff Dear John to something more complex, yet still logic in operation.

18 That calls for a lot of research for the components to be able to bring out of Searl's mind that which you cannot see. Therefore, you too can see what he states.

19 Searl appreciated that if he went digital in thinking and construction followed suit; he would be able to have multi-train control.

20 Up to 1968 Searl had just 14 locomotives operating over the same track.

21 One can appreciate that 14 trains running over the same track by the class of switching supplied at that time, is time consuming, and thus a slow process.

22 Not only children like model rail layouts, so doe's adults, maybe much more than children do.

PROF. JOHN ROY ROBERT SEARL

Author, Inventor, President, S.I.S.R.C.

Prof. Searl is the inventor of the **SEARL EFFECT GENERATOR, S.E.G.**, which is its own prime mover and generates electricity. He has written a series of books entitled “The Law of the Squares.”

Prof. Searl looks at things differently from most people in that he equates everything to “The Law of the Squares.”He is only interested in the Truth in all things. He has written his books to dispel all the miss-information and lies that have been written about him and his work.

He is setting the record straight. These books tell of his life experiences as well as the technology that he has developed. After reading these books, you may look at things differently.

He is currently President and Consultant Engineer of the ***Searl International Space Research Consortium (S.I.S.R.C.)*** Prof. Searl is truly trying to bring us into a better future through this method of thinking and the technology that it has produced. Sorry this is the end of chapter 17. May the power be with you always, take care; I am watching you watching me watching you the future looks bright turn up the light and be seen.

THE LAW OF THE SQUARES.

By Prof. John Roy Robert Searl.

The law of the squares states that all things within this universe have two prime states. They are opposites of which one will be greater in value than the other.

The law of the squares also states that there is a division between these two states.

Throughout my books you are shown hundreds of these samples. The one I shall discuss here is in reference to the animal termed Homo sapiens – that is correct, it represents you and me.

Let us look at the law of the squares statements:

1 There will be the non experts that representing the higher value.
2 There will be experts that representing the lower value.
3 Between these two states is a very small dividing line of inventors.

Thus the law of the squares is up held.

4 The non experts live in the today, not the yesterday nor the tomorrow.
5 The expert does not live in the today but rather in the 1,000 to 5 years of the past.
6 The inventor lives in the tomorrow, for he or she creates the future that is to be.

Without inventors there would be no tomorrows but a continuation of the today, thus never changing in any manner except for the change of seasons.

Inventors are labelled as living in a world of fantasy, while the so called experts claim to live in a world of reality; ironically, that very claim proves that their world came from the world of fantasy by those who suffered and struggled to create the present reality that these experts claim as their right.

Before any one can conceive a concept to generate some new invention a number of triggers have to be in place.
.

1. The brain must be free from all conventional brainwashing so that the sub-conscious can freely communicate to the conscious mind. Thus between these two states the data stored can be made active by the correct input of our body's sensors.

2 There must be information stored in the brain either at the time of its conception or gained after birth at the expense of time.

3 Once the correct triggers have been stimulated so that the conscious or sub-conscious mind can start searching and assembling a dream or a thought wave, data makes its way to the conscious mind of the owner and impresses the owner with the possibility of creating a new project.

4 It is extremely unlikely that you can invent because the brain that creates does so based on information that was invented already by brains of the past; even as far back as the day man first appeared upon planet earth.

5 My work is based on the success of hundreds of inventors before me; my work has just extended their work. They invented the materials, tools and equipment that make it possible for me to extend their work.

6 Within the laws of nature there is nothing impossible except that the state of your mind makes it so. And it is your mind which has and still does delay progress for a better world then we have today.

7 In my case; the sub-conscience assembled an extremely simple game which strangely contains the mathematics which is required to achieve this technology, without that input there is no S.E.G. or I.G.V. Anyone making such claims is talking out their rear end, what a shame to waste such energy.

8 It also gives much information on science and technology, which was a blessing as I had no need to go to school to learn it.

9 The device is basically a linear motor riding on a magnetic bearing; in reality there are three such units in one body.

10 Its characteristics are similar to that of an autotransformer; again three such devices in one body.

11 From the inner unit which generates its own output that feeds into the second unit that is also generating its own, but much greater output, is therefore boosted vastly by the input from the first unit. The second unit output is then feed into the third unit which also is generating a much larger output is again vastly increased by the input from the second unit.

12 Every operation of the S.E.G. follows Newton's laws precisely, these experts' claims that it is not possible are just protecting their image of importance. Such has always been the case since this animal called Homo sapiens arrive upon the planet earth and will always exist until the end of time.

13 Not only is the problem to design and test the specialised equipment to undertake this research; but one of the real major problems is that there are far too many of this species that suffer from an obsessive compulsive disorder that functions on ignorance and greed. There is no more dangerous combination that has so far managed to delay this technology from reaching its marketplace, and would had done so back in 1968 and again in 2003 if it was not for the effects relating to this disease.

14 Today for the fifth time efforts to recreate this technology are moving forward but cost is the greatest problem which increases each year that it takes to reach the marketplace. There is yet another major problem for delay. This is that the man involved has to live and therefore has to maintain a job by which he can survive and find from his pocket that cost which is involved. Time is related to availability of hard cash and spare time to work on it. It also requires absolute dedication and devotion and faith for its success and this man has all three requirements for such a success.

15 This world is dying from pollution factors which this technology offers a solution that no other technology can offer. Yet everyone ignores its possibilities because the power man of today would loose profit by such a technology being available on the marketplace.

16 Yet it would slowly halt this hurrican forming problem now greatly being experienced along the U.S.A. coast line, which will eventually reach places like Canada and even the UK if we allow this global warming to increase.

17 Is it humane for life and property to be destroyed in the name of ignorance and greed?

18 You may wonder if the S.E.G. output is Direct Current or Alternating Current. It is an Alternating Current at very high voltage that has to be passed through a step down transformer for the voltage required like all other power systems available today; current is proportional to the voltage.

19 Rare earths play an important part in the success of the S.E.G. operation. The one that has become the keystone of my work is Nd because everyone wants to follow the same one that I used in 1946. It is far from the best but it is the first choice for cost and availability.

20 One major problem is that it looses electrons to the air. As such it will oxidize in air. This can be prevented by the following means:

1. Keep it in argon while not in use which is the better choice; or in oil which is the choice that I do not prefer.
2. Or mix 1% of another rare earth which does not loose electrons to the air that will block the Nd from loosing its electrons to the air.
3. As you move up the element chart there are better options to use. Also it makes the S.E.G. smaller for the same output.

21 To experts it's impossible as they had stated about the cycle, motor car, Train, Plane, Electricity, gas, telephone, and television and space travel plus everything else made or done by man, in reality they were confirming that it could be done, and it was only done by those who lived in the world of fantasy, for it is only such people who are capable of free thinking by which progress in advancing man's knowledge can be achieved.

22 Everything made by man came out of the world of fantasy which existed there before man ever appeared on earth including all inventions of the future have been here since time began. But before any such invention can be brought forth from the world of fantasy into the world of reality some ingenious person must tune in to it; that action requires a set of triggers in a precise order of events and then and only then will such products become available to mankind.

23 Though the S.E.G. is a marvellous device it can only reduce the pollution problem which helps to reduce global warming that will give trees and animals a chance to survive. It will require everyone to help to clean up this planet as we made the mess due to our lack of knowledge and understanding and replant trees which in our ignorance have been cut down. These are urgent requirements to block the creation of hurricanes and tornados.

24 It takes about 30 years before a tree can fully function in its duty cycle in reducing this global warming, clearly the need is present today to start a massive replacement task in the effort to balance nature to our advantage, otherwise it will be to our disadvantage.

25 If you really care for your children's health and well fare then you must act today and help clean up these problems, To assist me to do my best to help nature to recover from our wrongs which we have done and are still doing.

26 Listen to our children who have no tomorrows if we don't care; our ignorance and greed is killing this planet. If we don't stop our destruction of this planet there will be no tomorrows for anyone. There will be just a resting place for our remains.

ANTIGRAVITY: THE DREAM MADE REALITY
THE STORY OF JOHN R. R. SEARL
BY: JOHN A. THOMAS, JR.

This book contains information that was received by me from John R. R. Searl about his life and inventions. Searl has had an antigravity device since 1946. He also developed a generator of electricity that uses no input power as we know it.

There has been much written about Searl and his work but most of it is misinformation or guesswork. Many people have tried to duplicate his work but none have succeeded. All information in this book is correct and directly from the source, Prof. John R. R. Searl himself. This book is the story of a man who is trying to move the world into the future... and has been for years.

John A. Thomas Jr.
Author

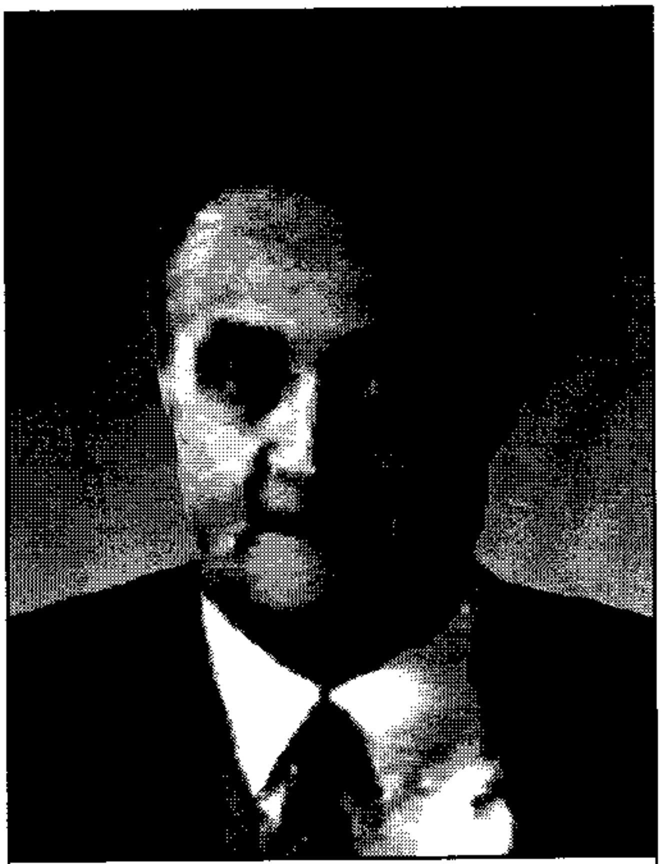
Mr. Thomas has a technical background in electricity and process control. He has studied such varied topics as UFO's and Ancient Technology that has been lost or forgotten.

He has carried on the efforts of Mr. William Sherwood, formerly Professor Searl's contact and help mate in the National Space Research Consortium (NSRC).

He first contacted Professor Searl in 1990 and since that time has printed and distributed his books on "The Law of the Squares".

John has been a student of Professor Searl and has come to an understanding of "the square technology" which is the basis for the Searl Effect Generator (SEG) and the Inverse-G-Vehicle (IGV). This book is a reflection of that learning process.

John is presently Vice President of the Direct International Science Consortium (DISC) and is Technical Representative for Professor Searl.



Prof. John R. R. Searl
Inventor

When I first called Prof. Searl I was apprehensive as to how I would be received. I was delighted to find him very receptive and eager to talk about his technology. We became good friends in the years to follow. I have never met such a sincere and honest individual.

Prof. Searl looks at things differently from most people in that he equates everything to "The Law of the Squares". He is only interested in the Truth in all things. He has written his books to dispel all the mis-information and lies that have been written about him and his work. He is setting the record straight. These books tell of his life experiences as well as the technology that he has developed. After reading these books you may look at things differently, as I do now.

He is currently the President and Consultant Engineer of the Direct International Science Consortium (DISC).

Prof. Searl is truly trying to bring us into a better future through this method of thinking and the technology that it has produced.

I have now started to release all past reports, statements made by me since 1946 up to the present time, this includes the data released within newsletters upon my work. Lectures etc.

These books contain the story of my life and those who were or are involved, they show letters connected with me upon this matter. Note that I alone can hold the copyright upon my life, what I state or do, no one else can do so.

I have given the rights to RAUM & ZEIT and NEXUS to write upon my life or work as and when they feel the readers would be interested in such matter.

I have accepted Mr.John A.Thomas Jr, as my represntive, and he has been given the rights to write any article he wishes upon this matter in the effort to push this technology right to the market place.

Now I am quite aware that many people since 1984 have written upon my work but have never paid me a penny for that right and many have not even asked me for the right to write upon my work. Slowly I have received copies of their articles from good people who have brought the matter to my notice. Many of these article I do not know who have written them, most contain details which are from the world of dreams. Therefore they wrote without my consent and rubbish, it is my duty to all those thousands who have helped me to correct this position NOW, that is precisely what I am doing.

If any one is stupid enough to make claims that I have copied they rights they must be prepared to be torn to pieces in a manner that will make newspapers have a hayday. I am a tiger, and boy, if I get you in court, I will give the court the best laugh of their life. I will rip you to pieces, I will bounce you so hard that you will never stop stuttering for a very long time.

I have so far shut my eyes to those writers who have written upon my work or claims, but the time has arrive that I must stand up and be counted, that is my humman right, now at last I am taking that right to be heard as a FACT, now I shall clean up the shit that has been thrown around the world. A number of you want like it, but that is precisely what I intended it is time that you received some punishment for your wrongs.

Any letters from you will appear in the next book released with whatever action that I have taken in relation to that letter. So it is far wiser that you don't send any such stupid letter to me. I mean to expose those who make statements with intent to turn people off from helping me. You should not be that stupid, so don't cry to others if you see that I am making fun of you, you asked for it, and I am certain that I will give it to you.

While I write and speak the truth, no man will stop me, that is a FACT, a point which you should accept immediately. If you think that I will not hear about the bullshit you are passing around, you are very much wrong it will come to me, that is a fact, and to prove, it will appear within these books for all to see that I do know about it.

The information contain within these books are precise at the date which it is listed, all information released has been released by me unless its an article by some other person upon me, whose name is quoted, or person unknown at this time. If their name become known to me I will quote it in the next book released. No doubt some one will know who wrote that article. Any article written about me will appear within these books, because that happens to be my copyright, my life not yours. You have not paid me any value for that right. I don't care if you think you got right, you have not, and in court I shall demand a heavy price for failure to secure that right. Therefore, unless you have a lot money available to pay me, just shut up, and keep quite, so I don't hear about it.

I have no intentions to create trouble for any one, unless they go out their way looking for it. My whole intentions, as it has always been, is to try to unite all those who work upon ideas of cleaner energy systems, no lecture have I given where I have not pressed that point calling all inventors to group together, to work together to success. The choice is yours.

Please note that the contents within this book is precisely correct to the best of my knowledge. The contents are related to my work, directly or indirectly. All information is vital to my future achievements. All statements are made by me unless it is stated by some other person/s.

My release of data started as newsletters and lectures from 1946, now all this information of the past, present and future, is being woven together into a book format and released. It deals with my life and those who are involved. My work, my education and knowledge and how I employ that knowledge.

My life cannot be copyrighted by anyone except myself. Therefore, I have appointed Mr.John A Thomas Jr. as my representative with premission to write articles upon my work in the effort to speed this work to the market place.

I am quite aware that people have written upon my life without my permission, who have not paid me one penny for that right. I have shut my eyes to that offense, and will continue to do so, unless they wish to make any rows about me quoting their article and pointing out what is wrong with it...THAT IS MY RIGHT...NOT YOURS.

Any such offensive letters being received will appear in my very next release with what ever action I have taken. I mean to clean the shit up that has gone out upon me, and I will. If any one is stupid enough to write me or others, statements of claims which are unfounded, watch out, I am a tiger and I will tear you to pieces before the public. It is my RIGHT and DUTY to all those who have helped me over the years, to stand up and be counted, and that is precisely what I am doing.

I have given authority to both **RAUM & ZEIT** and **NEXUS** to write upon my work whenever they feel that the public would be interested upon such matters.

I have given authority to societies who have given me time to lecture there, in the interest to bring more people to one place, to write upon my work in the manner to which they feel would interest their readers.

Today, to my knowledge, I am the only person, who within my lectures, plead for all inventors to join together as a group to develop tomorrow's technology. This way progress would be speeded up, thus the media will stop mocking you. But if you like being mocked, then just remain an individual.

This set of books have been released upon the authority of

MY MEDICAL KNOWLEDGE DISCUSSION 183

All contents within this book are correct at the time they were released, and cover my life, my knowledge and how I employ that knowledge. These books cover articles which I have released over the years from 1946 to the present date as newsletters or lectures given by me, which is now being issued in book format.

As I am the only person who can copyright my life, and my life's work, therefore, there is nothing which I can released which relates to any other person copyright, as they do not have one upon me or my work. Any person/s making such claims are in fact in breach of my copyright.

I am quite aware that there have been, and will be those writers who write upon me or my work, which have had no authority from me to do so. Nor have they paid me any value for the rights to release such information. I have shut my eyes to this offense, and will continue to do so, unless they are stupid enough to make claimes that I have stolen their copyright's, then I have a duty to all those who have help me to stand up and be counted. You will find that I am a tiger, and a powerful one at that, and will tear you to pices in public.

TAKE WARNING : any stupid letters on such subjects shall be released in the very next book that I release with whatever action that I have taken in response to that letter. for all to see. I have a task to undertake, and let no one be mistaken upon that point, that I am not capable of undertaing it. The task to create clean cheap energy, and better transportation systems, and better homes for all mankind is a must, it can be done, and it will be done. I shall take whatever measures are deemed necessary to get this technology to the market place.

What ever I write within these books are matters which are related to me or my work, directly or indirectly, are of my own statements unless stated as being an article by another person/s known or unknown. Any statements which are claimed by anyone as there's are simly talking out of their arsehole. If they have made such statements they did so without my consent, therefore they are in breach of my HUMAN RIGHTS.

Therefore, I have appointed Mr.John A.Thomas Jr, as my legal representative. who has the authority to write reports upon my work. In the effort to speed this technology to the market place.

I have given authority to RAUM & ZEIT and to NEXUS to release articles whenever they feel that the public would be interested. Authority has also been granted to Societies where ever I lecture to write upon my work or lecture given. In the effort to unite inventors and researches together.

To my knowledge. I am the only Inventor who at my lectures plead with all inventors to join together in an effort to speed up new products to the market place. For as long as you remain as an individual the media will laugh at your claims. United we can work together, thus the media will have to re-think on what they say.

New cleaner power and transportation systems are a must, we all see things different, we all think different, but the time has arrived where we must try to think the same, see the same, work together as one large family, for our childrens sake if not for our own sake of survival.

Yours for a cleaner better world for all mankind.

This set of books are released so that readers can understand the truth about myself JOHN ROY ROBERT SEARL, my life, my knowledge, my skills, how I employ that knowledge, and what others have stated about me, and what is wrong with that statement. There is no copyright held by any one upon my life, except that of myself. I and I alone hold the full copyright upon my life. All this information upon my work has been known around the world since 1956. I have given lectures so often over those years. Therefore anything written by any person other than those which I have declared within these books, are in fact in breach of my copyright. Please take note. This is a public statement.

John Thomas Jr. of the U.S.A. has been accepted by me as my representative, he has been given rights to write upon my life from the mass of data which he holds. More will be supplied him in due time.

Others whom have been given the rights are RAUM & ZEIT plus NEXUS and all places or societies where I have been booked to lecture throughout the world. I shall continue to release the TRUTH at all cost. It is my life and not yours.

These books are released by the authority of

FIRST EVER PRESS PICTURE ARTICLE OUT approx.1967 411

The contents of this book are absolutely correct, unless an article is quoted as being an article of another person, they are my reports as seen through my eyes. based upon my knowledge and education.

I appreciate that some of the readers will have different views, if so write me your views or ideas, let me hear them, by keeping them to yourself achieves nothing. Airing them, might come up with something interesting.

I have within these books shown views of others. as they have presented them, right or wrong. they have a view. I repect that view, as their rights.

NOTE : QUESTION

WHAT IS THE ANSWER TO 4^2 ?

You know that answer, do you ? You think you do. Or you do know it ? I doubt if you do know the full answer, unless of course you have read and studied my books. You see, I know what answer you will give, which is 16, for that I would give you just 1 point out of 10 points for trying.

Each square has four main forces. is not symmetric. but only nearly symmetric, for if it was fully symmetric, the four forces would equal zero, there would therefore be no forces acting upon the roller. But the squares are only nearly symmetric thus the roller experiences a force acting upon it. So it ruddy well tries to move out of the way, and it does.

Please take note that **MR.JOHN A.THOMAS** Jr. has been accepted as my representative and has been given the authority to write upon my work, in the direct effort to push this technology to the market place.

ISBN 1 898827 25 7

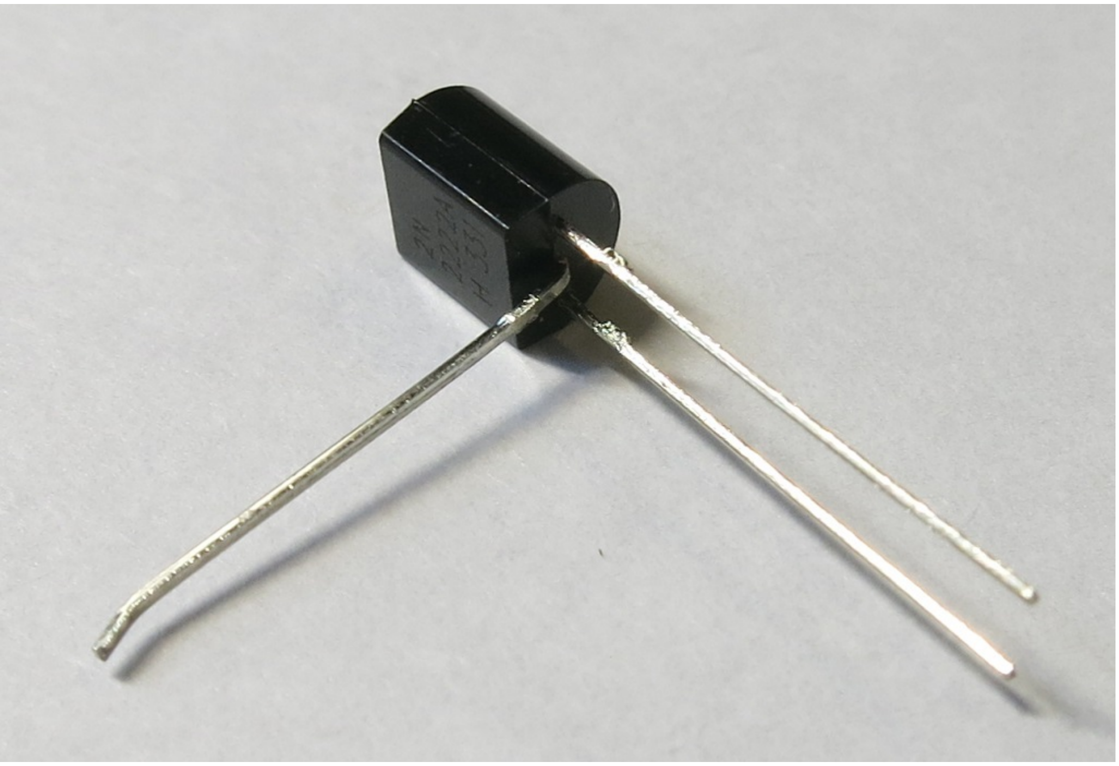
1. Minimize physical size. Since the coil is the largest single piece (other than the AA battery) it makes sense to align the diameter of the coil to the battery and pack everything else as tightly inside as I can.
2. Minimize component count. Most Joule Thief examples on the internet (including the top picture on the Wikipedia page) soldered the legs of the individual components together. No circuit board needed.
3. Friendly to hand soldering. There are some ready-made Joule Thief circuits for sale on the internet using surface mount components and a circuit board. I wanted something I can build by hand and maybe use as a soldering teaching project to be shared on the internet.

After a few iterations, I have something I'm happy to share with the world. This is purely about the mechanical assembly – the electronic schematic is identical to the one in the Wikipedia article linked at the top of this post.

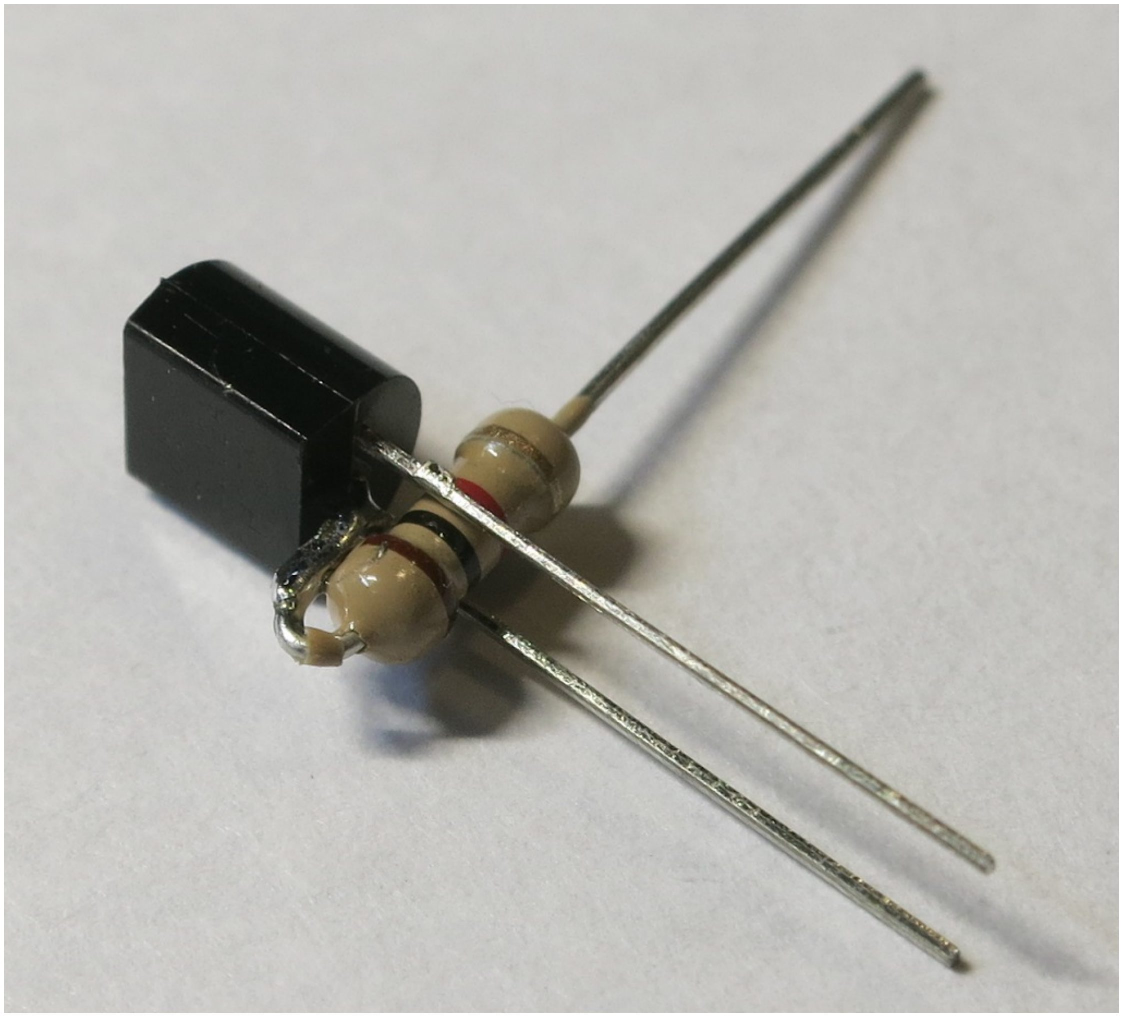
An overview in words:

- The resistor for the NPN transistor base is installed between the collector and emitter. The resistor acts as physical separation in order to avoid a short-circuit.
- The transistor and LED are pointing in opposite directions, allowing their pins to point towards each other and soldered together. The aforementioned resistor keeps the LED anode and cathode separate.
- The transistor is stuffed into the middle of the coil, utilizing the center volume.

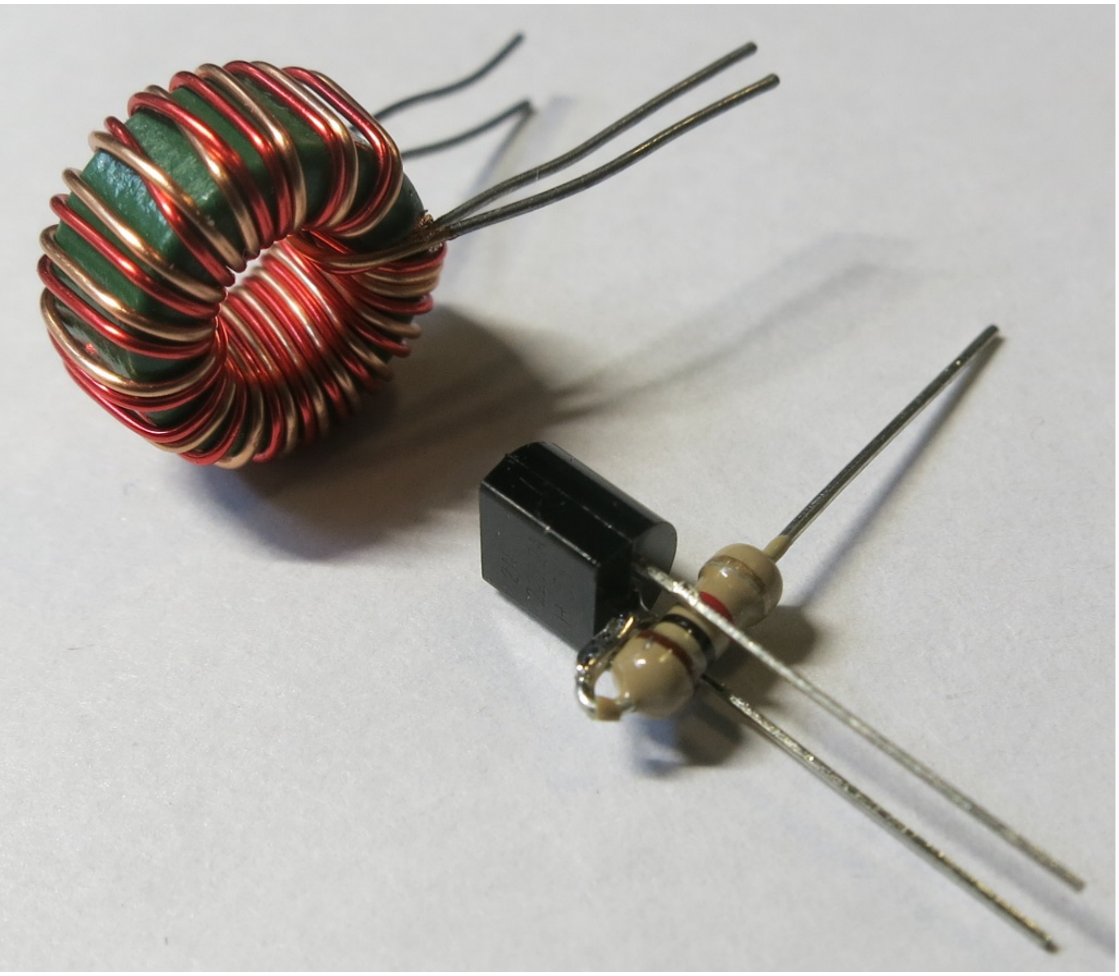
The build sequence in pictures:



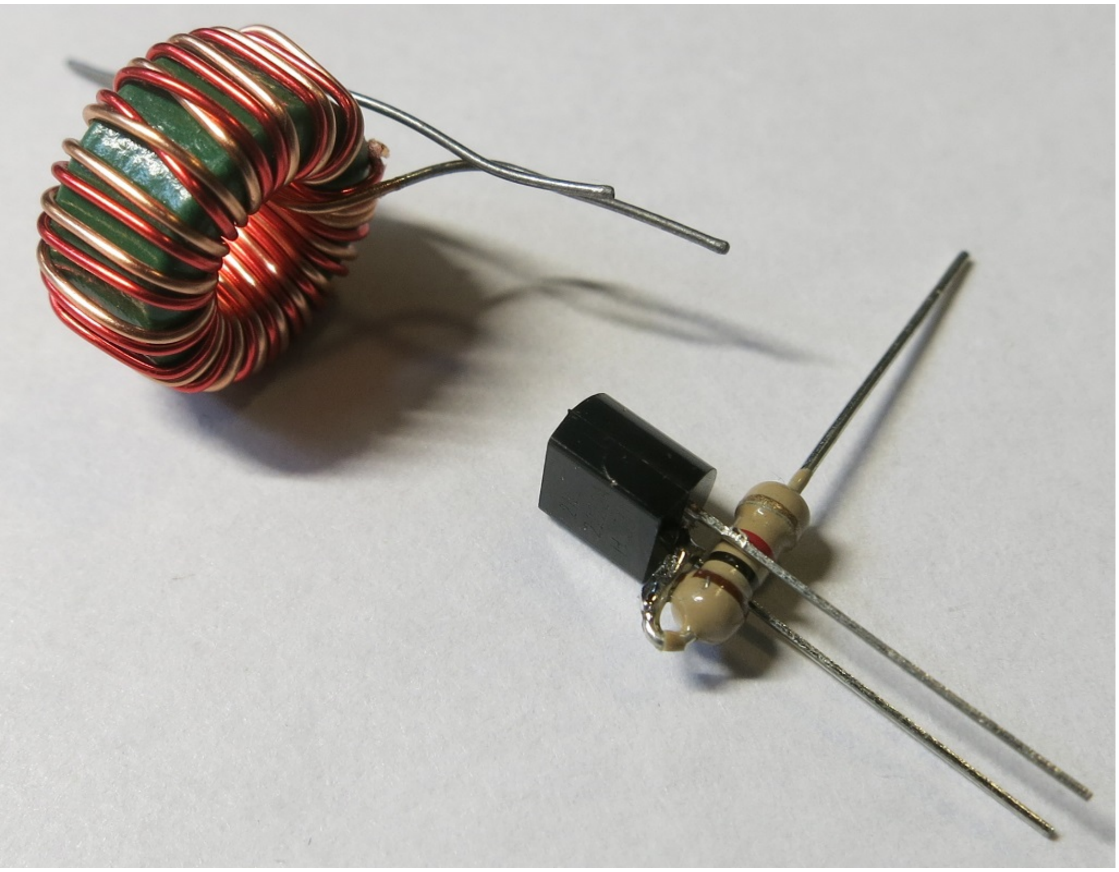
Transistor with the base bent in preparation for resistor installation.



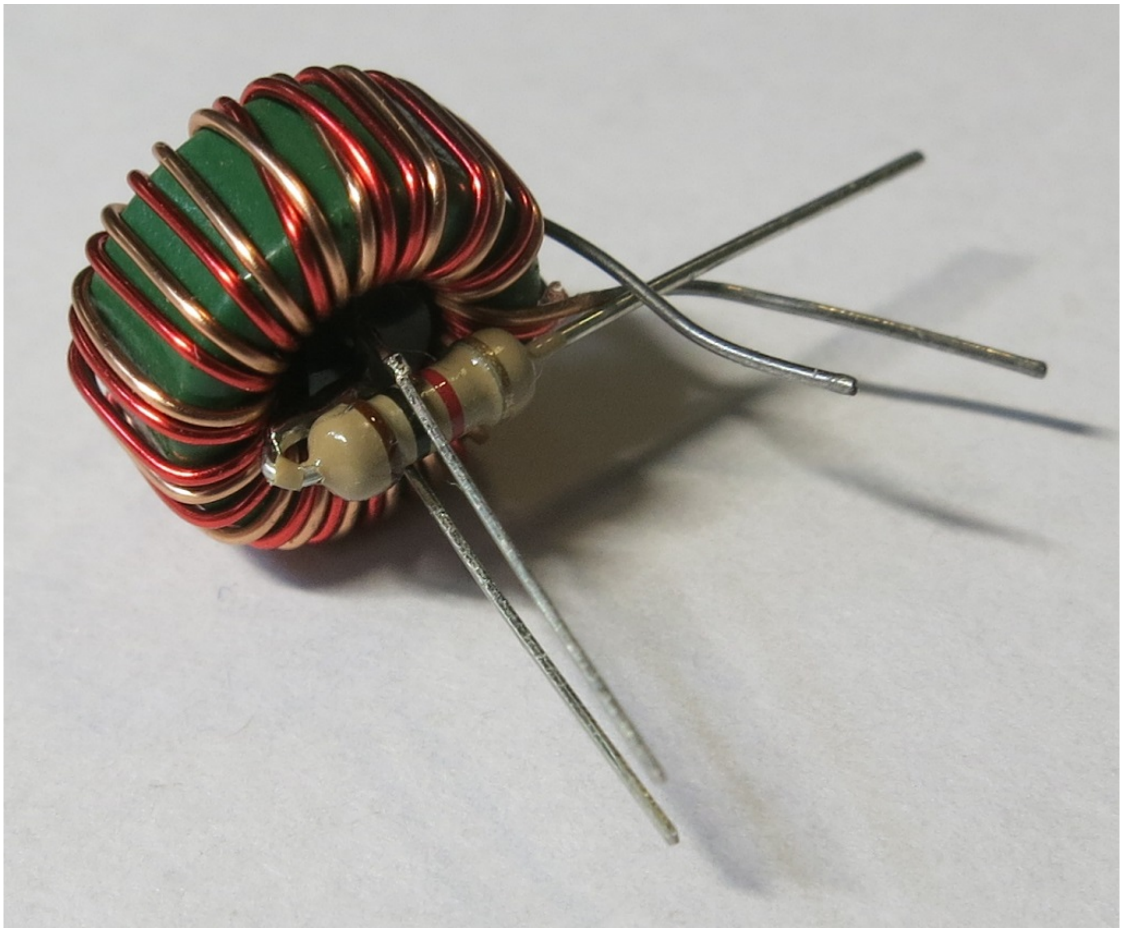
The 1K Ohm resistor is installed on the base, between collector and emitter.



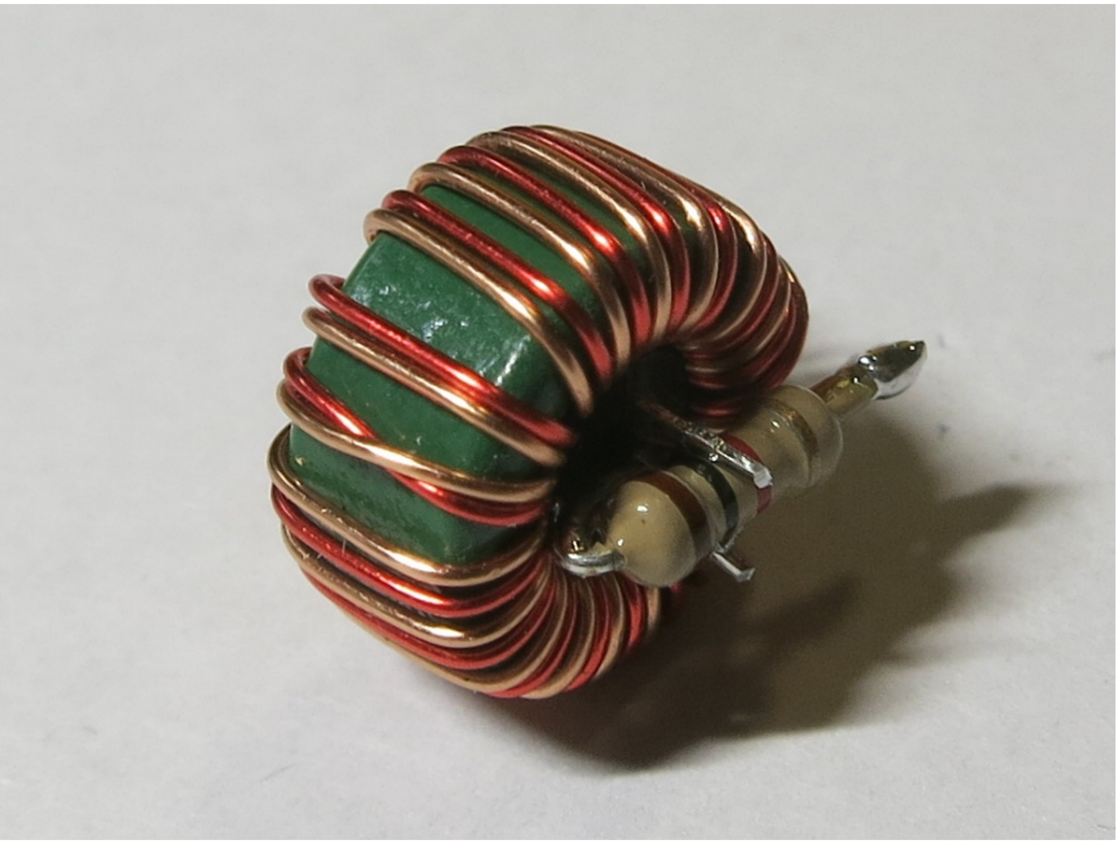
The coil has two wires wound together. One end of this dual-coil is facing the camera, the other end facing away. Since we need to wire up the coil in opposite directions, we'll bend one wire of the front pair towards the back, and the opposite back side wire to the front.



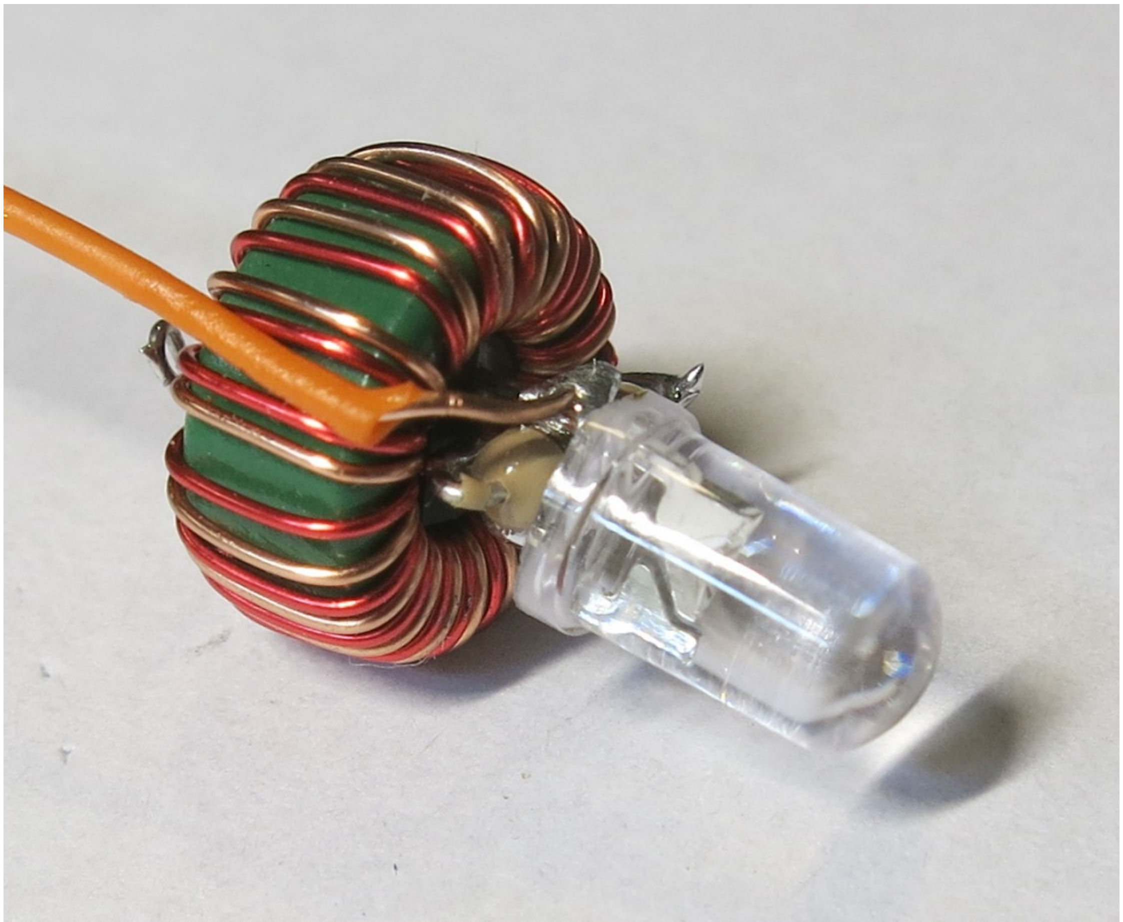
The two wires now facing away from the camera are soldered together to become the positive terminal of the circuit. One of the two wires facing the front will be soldered to the resistor, and the other to the emitter.



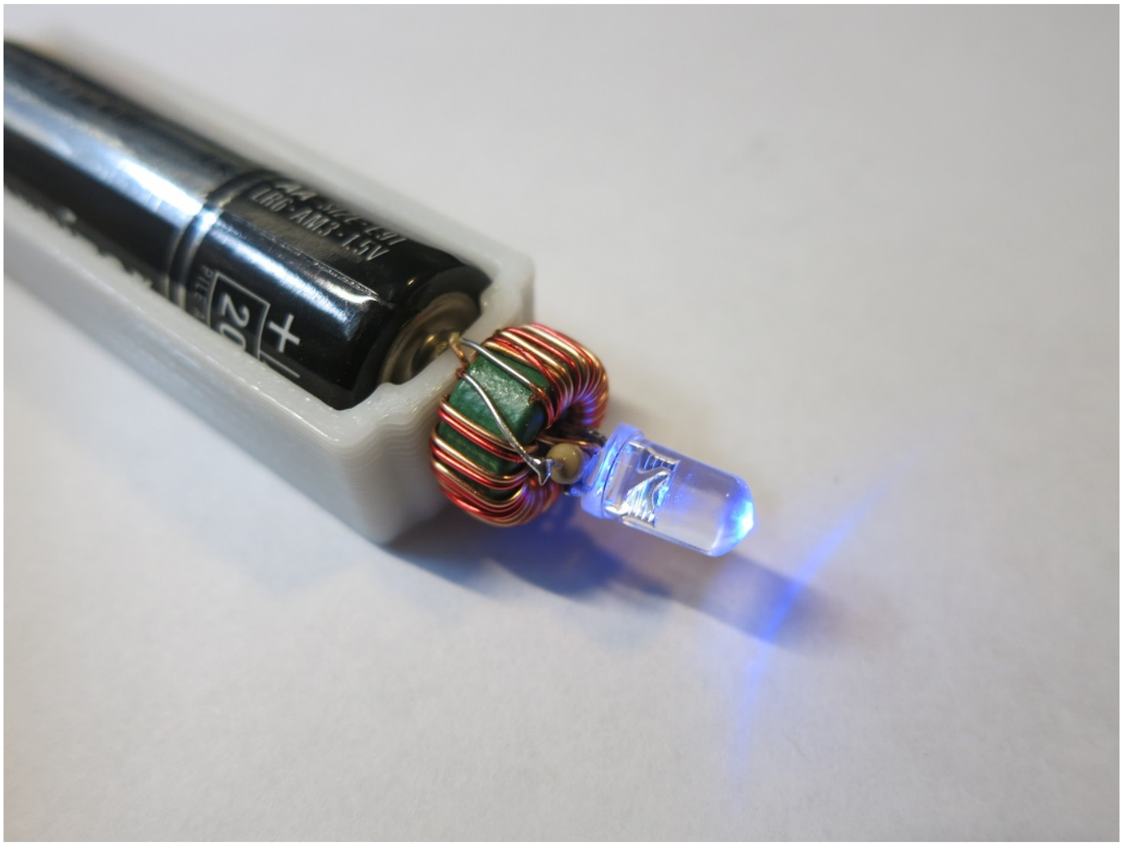
Transistor in the center of the coil. Now the coil wires can be soldered.



Resistor soldered to one coil wire, all the others have been trimmed short in preparation for attaching the LED.



LED is soldered to the circuit, as is a wire to act as negative (return) wire.



Install the whole assembly in front of a 3D-printed AA battery tray: Let there be light!

2017-10-192017-10-19 / **ROGER CHENG**

A 3D-Printed Enclosure to Take My LED Project On The Go

For the **Connect Week (https://connectpasadena.com)** event put on by **Innovate Pasadena (http://www.innovatepasadena.org/)**, the **Hackaday LA (https://www.meetup.com/Hackaday-Los-Angeles/)** group is hosting the "**Bring-A-Hack (https://www.meetup.com/Hackaday-Los-Angeles/events/243694093/)**" event where attendees are encouraged to bring projects (in any stage of completion) for show and discussion. Since I've been building my LTC-4627JR driver board as a learning project, I wanted to bring it in for show-and-tell.

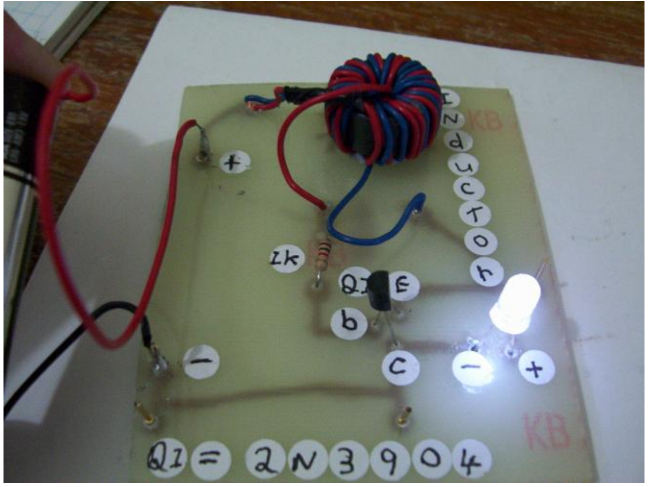
Now I could just bring the assembled circuit board and pass it around as an inert object, but what fun would that be? I wanted to bring in something that shows it doing something, and provide some way for people to interact with the whole contraption. Looking at my parts on hand, it seemed easiest to rebuild my thermometer test project. I can have a simple Python program run on the Raspberry Pi, reading temperature from the Tux-Lab Si7021 breakout board, and sending it out to my display. That makes 3 circuit boards, plus they'll need portable power. I will enlist my Amazon purchases: the 3-cell lithium ion battery pack protected by a S-8254A IC, and the MP1584 buck converter to translate the battery pack's power into Raspberry Pi friendly voltage.

Making a Joule Thief Charger Circuit with Steven Chiverton

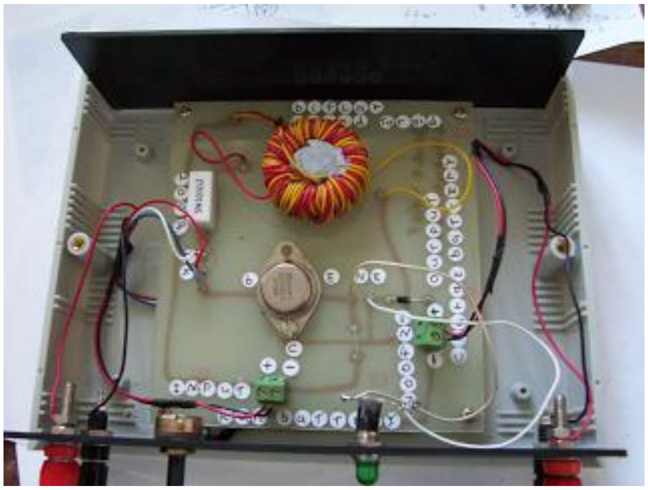
Posted by hitman

Continued from the previous article

Here is the joule thief used to test my button cells out after I successfully recharged them.



Here's my battery charger joule thief all installed into a circuit box.

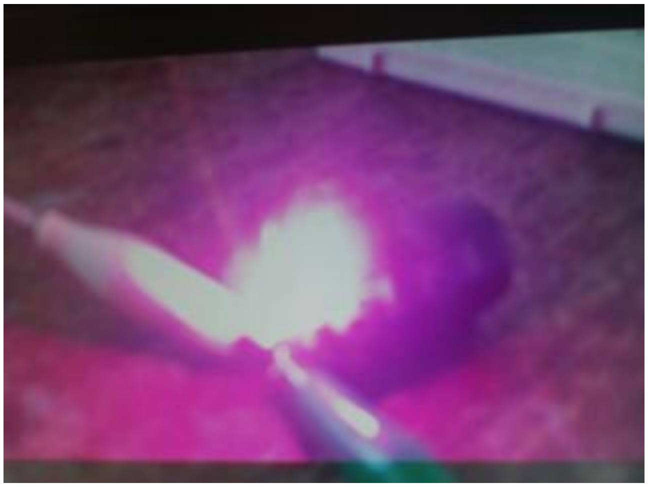


Below is the front view, notice the 12 volts green light at the front panel that is modified to house a neon globe inside it.

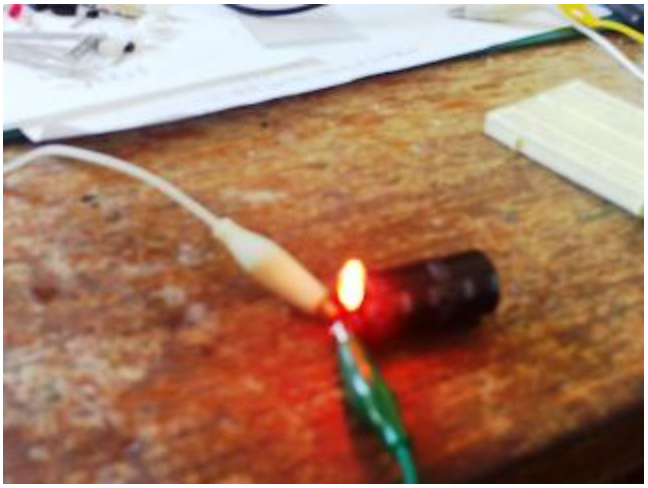
While looking through my electronics parts draws I found another 7 or 8 more button batteries and some had charge still on them and some I recharged successfully and 2 couldn’t be charged anyhow a few small ones took a little zapping to get them to take a charge so maybe if they are got some sulphate in them if not then why did it take so long to get them to except a charge.?

Yesterday I found another button battery cell and after a few seconds charging it started to get warm so I stopped it before it got to hot otherwise it would explode
Now I have 24 button cell batteries.

Below is a picture of the bright white with pink flash of a photo flash capacitor neon circuit test The outputs of my battery charger joule thief run to the 330 volts photo flash capacitor, and across its leads I placed a neon bulb, loosely so every so long you hear a spark jump but cant see it unless the neon leg is getting pulled in by the high voltage attraction then a short time after that the flash occurs, so if the neon is rated at 90 volts then the cap charge may be the same till it charges up more I filmed this then put it onto my pc and then I had to slow it down so much to capture the super fast flash then pause it then take a picture of it to load back onto my pc.



Here's what it looks like when it aint flashing



ive soldered one of the neon legs to one of the high voltage 330 volts photo flash capacitor legs and the other neon leg I had it just nearly touching the other capacitor terminal but I didn't get the arc and flash after it like I got before .
next test was running one of my jumper leads to a folded peace of aluminum foil and back to the hv capacitor and the other lead I ran to the other hv cap leg to a pencil and when the neon at the 330 volts 2200uf photo flash cap come on I gently touched the lead pencil tip to the foil edge where its folded and I got flashes etc and tiny holes melted through it and when I tried to unfold the foil it was stuck like it was spot welded , and there sure was this horrible smell made by spot welding aluminum foil.

Next experiment was running the leads from the capacitor to 2x 316 grade stainless steel bolts in a jar of tap water to create any electrolysis effects and I got very fine misty vapours come up to the top of the water and no bubbles and even when the bolts slipped together I was still getting it and even when they are apart to, and the further apart the bolts are the lower the frequency of sound is emitted from the battery charger joule thief and the closer the bolt electrodes are the higher the frequency of the sound the circuit emits gets ,

My watch battery I charged before has stopped I guess the charge didn't last long enough, I charged it on the 24th may 2010 and it lasted till today at 8past 8 , either in the morning or last night , so it lasted a week only im gona try re charging it again . Also today at the shops I went to the place they do watches and shoes and there was thousands of button cells inside this Perspex box even large ones next to it , but no one was there to answer my questions about them .
Ive recharged my watch battery again today but I was charging it the wrong way around so I got it right after that now my watch is running again so ill see how long its lasts for this time. Today is June the 1st 2010 so lets see if it lasts a week, also if it lasts longer then it may be the reverse charging that contributed to the extra running time before I charged it right

I scored a packet of free button cell batteries including large lithium cells and a few small 12 volts pencil batteries for free from 2 places in Armadale that also replace watch batteries, they have thousands of them and I counted what they gave me in total I had 85 batteries mostly button cells and ive successfully recharged them all except some lithium large button cells so also my 25 batteries I had it makes 110 batteries in total including the few large lithium cells that couldn't be charged or revived at all some of the batteries still had power in them to .

Half the button cell batteries couldn't maintain there charge and went flat overnight
So I recharged them again so ill soon check to see if they hold there charge this time also I dismantled a lithium battery it has a thin white membrane that reacts with water and foams up and also a thicker black membrane with what looks like very thin silver wire looking cross patterns on its sides and when I dismantled that battery it sure stunk inside it to
Today Tuesday June 8th 2010 I decided to use my 4 rechargeable batteries from my camera to power my radiant joule thief battery charger, to restore my 12 volts 7.2 amps an hour 20 hour sla battery, and so after an hour or so I used a pair of tweezers to short out the battery terminal and I got some sparks where I didn't before that, so I left the joule thief battery charger running all day today and now when I plug in the battery charger the red charging led light doesn't go to green after a short charge that's trickle charge, when green its still on red so im looking forward to how it goes when fully charged then in the green when its charged so if I get plenty sparks when I short the battery terminals then I can say the battery has been revived .

My 12 volts sla battery appears to still have a tiny bit of sulphate on its plates as its voltage dropped 0.7 volts over night so when the battery is low and needs topping up ill put it back on the joule thief circuit.

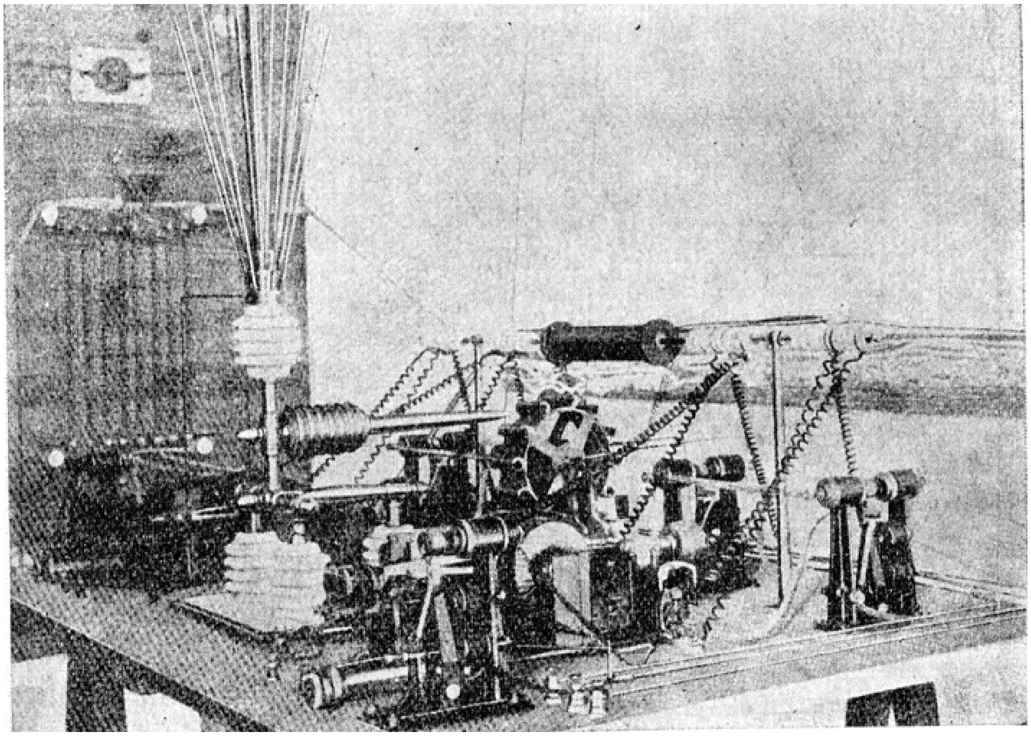
Jules GUILLOT

Atmospheric Electric Generator



Shared by L. Cozma (Thanks !) --

The Guillot device generated about 2.5-3 Kilowatts with antenna height of ~ 20 meters. Power depends on the total collector surface and height of the vertical antenna. The apparatus in the photo produced ~300 watts with a collector 2 meters tall.

"Practical Utilization of Atmospheric Electricity"

by

Gillbert Darida

in *The Invention Encyclopedia*, pp. 204-207 (1930, Geo. Constantinescu, Ed.)

"The Earth has its own negative electricity, in the soil, and the atmosphere which surrounds the Earth is charged with positive electricity. The electric potential (the voltage) increases with the altitude, so we can say that the electric force is proportional to the atmospheric altitude (after Franklin, Quetelet, Lord Kelvin, Mascart, Joubert and other scientists).

The recent observations demonstrate that the air at 6000-7000 meters in altitude, is very highly charged with positive electricity, which could be explained by the friction between the external photosphere and the upper atmosphere of Earth, which rotates at a speed of more than 100,000 Kilometer per hour.

In that way, the Earth works like an electrostatic generator with electric charging by influence --- the upper atmosphere is positively charged by influence and the Earth crust obtains the negative polarity.

Between the two environments, the air and the soil, and inside the low atmosphere, in conditions of good weather, there are sbout 800 positive ions and also, 680 negative ion (and electrons) in just one square-centimeter of normal ionised air.

The Earth behaves like an huge electric armature negatively charged, which repels the electrons and attracts the positive ions. That positive ions' attraction determinates an electric current, also called "convective current". That's like an invisible continous bombardment, subject to daily and seasonal variations, which could be aproximated at **3 x 10 ^ -16 Amperes per square-centimeter,** and that is a total value of 1500 Amperes for the entire surface of the Earth.
The question is --- how does this current always maintains the same direction ? We can suppose that the natural radioactive emissions of the soil is responsable for this. We also know that radioactive emissions of the Earth works usually near the soil surface, and that explains the ionisation phenomenona inside caves.

The ionisation of the low atmosphere could also be the effect of the radioactive emissions of the Earth, especially when the X radiation works. Also, the Earth atmosphere is ionisated by the external radiation proceeding from the Sun and from the space environment, especially the action of ultraviolet radiation and the electron fascicles emitted by the Sun surface, at the temperature of 6000 deg. Celsius.

The capture of atmosphere electricity has been used in France, with aerial cables mounted on the Mont Blanc, and also in Germany --- with conductive cables carried by the captive baloons.

The atmosphere electricity collect system invented by eng. Jules Guillot is most ingenious and it relies on "the **electric siphon**" [*m.n. --- the discharging devices or spark-gap used today from the protection of aerial electric cables against the atmospheric electricity ; Jules Guillot has thought to recuperate and to use that electricity*].

His method consisted in the direct "pumping" of the atmosphere electricity using a collecting device which had two antennae and several collecting rods.

One antenna is **vertical** and it has a lot of **rods** scattered like an opened **fan**, with the tips against the **zenith**, for collecting the **negative** electricity which comes from the air ; the **horizontal** antenna is orientated against the **South** and its role is to collect the **positive** electricity.

The air electricity seems to have the double-polarity, as we can see at two electrised clouds when between them apears the electric discharge. The air could have different electric charging and the ionisation processus of atmosphere is very heterogenous. The inventor Guillot used **two separated and insulated armatures with the positive armature against the South** (more precisely, against the **Equator**...) and the **negative** armature against the **zenith**.

We can see in the scheme :

1,- the device P is the "**collector apparatus**" having **15-20 meters height** ; it also has a lot of **rods** which are scattered **fan**-like, all this on top of an **iron pillar** ; and also an **horizontal antenna** S oriented against the **South** ; the two antennae are disposed at **90 deg. angle** forming the two armatures where the electrical tension must apear. As the **height** of the pillar **increases**, the **voltage** increases more and more ;

2,- a system of **lightning-rods** (p1, p2, p3) for protection against discharges of atmospheric electricity during storms;

3,- the regulator system (**voltage regulator**, etc) R ;

4,- the electric **resistors** (Cn) for absorbing the parasite currents ;

5,- the "electric siphons" which have the role of making a magnetic field as a good environment for the transport of the ionized fluid, absorbing the electricity from the air ; the E1 and E2 are their regulator devices ;

6,- an **auxilliary continous current power supply** which send the current against an special **excitation coil**, used as starting device ; it works only when the system is starting.
This collector device works very good for lighting and heating. The device made by Guillot had
20 meters height on the total surface of **3 square-meters**. Also, J.Guillot used and electrical transformer for the industrial utilization of this "collector" --- as power supply for industrial electric engines."

French Patent # 551,882

Apparatus for Capture of Electric Currents in the Atmosphere

16 April 1923

Considering the terrestrial globe like the inductor of a dynamo, where the extraterrestrial ether is the inductor of electric currents circulating in the atmosphere; the apparatus of the invention described here selects through the device described below two perfectly distinct currents and eliminates others.

The device includes:

1, The air sensor; 2, a series of lightning rods; 3, vacuum; 4, an array of resistances; 5, vacuum; 6, witnesses.

1. An aerial sensor mounted on a pole is composed of **magnetic steel** fixed and sealed by a porcelain **insulator**, and surrounded a base by a **bronze ring** which are screwed **32 points of soft iron**, all forming antenna a pole. level beside it and isolated from the first, forming the 2nd pole, is fixed a sharp point of magnetic steel fixed in the horizontal position and directed towards the south and **movable to an angle of 45** is sealed in a porcelain insulator. This point is also circled a **ring of copper** notches figure. 1.

2. A series of 6 lightning surge arrestors at corners between each pole and the earth and the various gauges.

3. A first **regulator** form of a device similar absolutely similar to the aerial amtenna, but the two poles are superposed and opposed to the vertical point, and a **copper disk connects to ground**. Opposite the horizontal point, a **ring of tin** to which are welded tubes alternatively **16 tubes** composed each composed of **copper-lead** and **iron-lead** . The ring connects to the **ground** as shown in figure. 2.

A second regulator form of **automatic breakers** balanced on 3 poles and two poles also equally balanced.

4. A panel of **resistances** composed of **wire mesh** in bunches from different sections of **glass tubes** containing **copper** dust, **coal** and flowers of **sulfur**.

Vacuum cleaners consists of a **wooden box** on each pole, containing a **porcelain vase** in which **layers** isolated with **mica** is made up of **mercury, tin, coal, copper** and **sulfur**, all contaied in a **copper tube**.

6. The witnesses are comprised of ordinary incandescent lamps.

Resume

By the point at the zenith and the point to the south we channel two currents forming the two poles. We also protect from lightning. It regularizes the flow by a regulator and similar devices by a controlling each devise of adequate strength of the current harmful nature of these devices do not have loads. The refined current is conducted by ordinary copper wires**.**

French Patent # 565,395

Combined Apparatus for Capture of Atmospheric Electric Currents with Immediate Implementation

25 January 1924

We know that earth with its constitution, its rotation and movement in space, provides the electricity in the atmosphere. The electrical currents escape into space or largely accumulate towards the equator, as a result of the greater periphery of the globe.

In the atmosphere, there are two clearly distinct poles, i.e., clouds that can be electrically positive or negative; everything in nature shows this, otherwise it would be difficult to explain the lightning that occurs between the clouds and which are none other than contrary cloud electrical charges discharged by too close proximity.

The invention relates to a set of devices capable of capturing the atmospheric electricity.

So far, all searches made for this purpose has been to capture the atmosphere, i.e., that brought together into one system to capture two poles and opposes effect has been to destroy or cancel each other leaving the amount as the difference of the strongest to weakest.

It is therefore easy to understand why, considering the two poles of air as about equal, it is almost impossible to measure some potential with the land, the highest on the lowest remaining which can be positive or negative, copper being the strongest of one or other of these polarities.

It is on this basis that all research until now have been made, and that is why we must consider that all the time, between the two poles captured in the atmosphere and not in any mixture of systems uptake, it is possible to obtain tension and intensity, a considerable and measurable power captured separately between the two poles and remaining isolated from one another until their utilization .

In accordance with this invention, this collection is made by attraction of primary electrical currents in teh atmosphere, either positively or negatively charged, by an antenna that has two points absolutely isolated from one another, where one points to the zenith to attract negative electricity, and the other turned south, toward the equator to draws in the masses grouped in this area.

This shows and proves the existence of atmospheric electrical currents, and that it is possible to capture them with specially designed equipment primarily acting as regulators, as the persistent difficulty encountered so far in realizing their capture lies with large variations of tension in which the current atmosphere is present in space, for each of the poles, and an overload could inevitably fatal.

The patent in its present form of presentation does not cover the regulators or devices that are anticipated in the system, because they can be designed in different ways and give the same result, but covers the application and grouping of equipment operating as automatic relays with variable influence to limit current tension to that chosen for utilization.

These devices have a role associated with an overflow reservoir outside carrying excess liquid; these regulators will divert the excess voltage flows to ground.

We can still absorb these regulators having filters because they have the sole purpose of diverting the post being used , currents that are not yet known but likely that we will call for simplicity, abnormal currents. [sic...]

The patent also covers systems for regulating currents, applied to each of the poles because it is recognized that the shape and tension of the currents of the two poles are not equivalent.

The method of capture is by special antenna has directed two points in the atmosphere, as will be stated after this, with Boot ecoulement prior to the current atmosphere is also of great importance.

Finally, the current atmospheric reception is adequate even with the installation of a post, which can be expected at any location without the need for special altitude, as has been attempted in previous efforts.

We refer to the attached drawings:.

Figure 1 represents in elevation and side view an antenna that only has two points, to overcome an elevation ;

Figure 2 is the end of one of the peaks, the horizontal:

Figure 4 is a scheme of surge arrestors, and

Figure 5 a table of resistances.

Fig. 4.

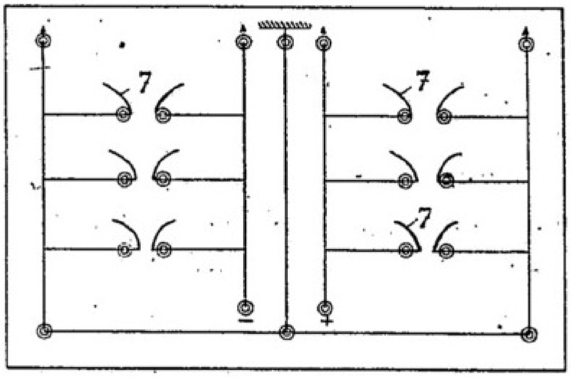

Fig. 5.

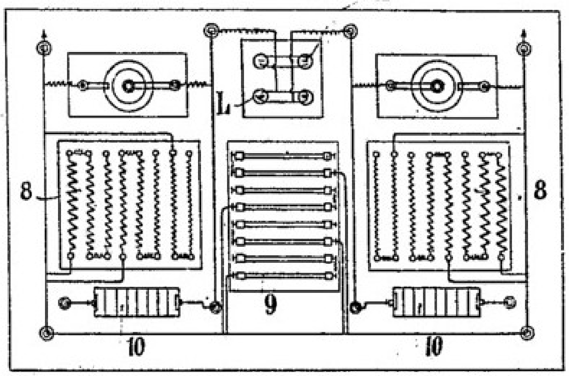


The necessary arrangements to capture atmospheric current form is as follows:

1. The **antenna** in figure 1 is formed with two peaks: the 1 is **steel**, supported by a **bronze ring** 2, surrounded by a **spiral form** 3; this point is oriented for attracting the **zenith** layers of **negative electricity** and the other edge 4 contains **copper coils** 6, and is oriented **south** to the **equator** to draw in the masses grouped in this area. To use this antenna it suffices to be raised on a mast or **pole** to a height a little higher than that of surrounding houses.

2. On the table **lightning arrestors**, contained 4, forms of 7 **copper horns** used to absorb large atmospheric discharges by certain time, as it would be dangerous to allow movement in the devices regulators.

3. On a table of **two** symmetrical systems **regulators**, Figure 3, one for each pole, to obtain and allow a regularization of large excesses in the current tensions, by automatically absorbing surges before passing over the surfacea chosen for the desired use. These regulators are represented on the drawing by the references R, R1, R2, R3, R4.

4. In the **resistance** panel in communication with regulators, these resistances are formed as **spiral coils or screens** 8, **tubes 9 of glass filled with fine coal dust , aluminum powder, sulfur and fine copper dust**. Finally, **two** special 10 **processors** and constitutes **layers** of metal forming an **absorbant** for harmful or abnormal currents.

5. As a source of energy formed **auxiliary batteries** 11 and **Ruhmkorff coils** 12 to get into the antenna sufficient attraction by means of an adjustment of intensity, which once it begins, allows the constant flow of atmospheric current in the system.

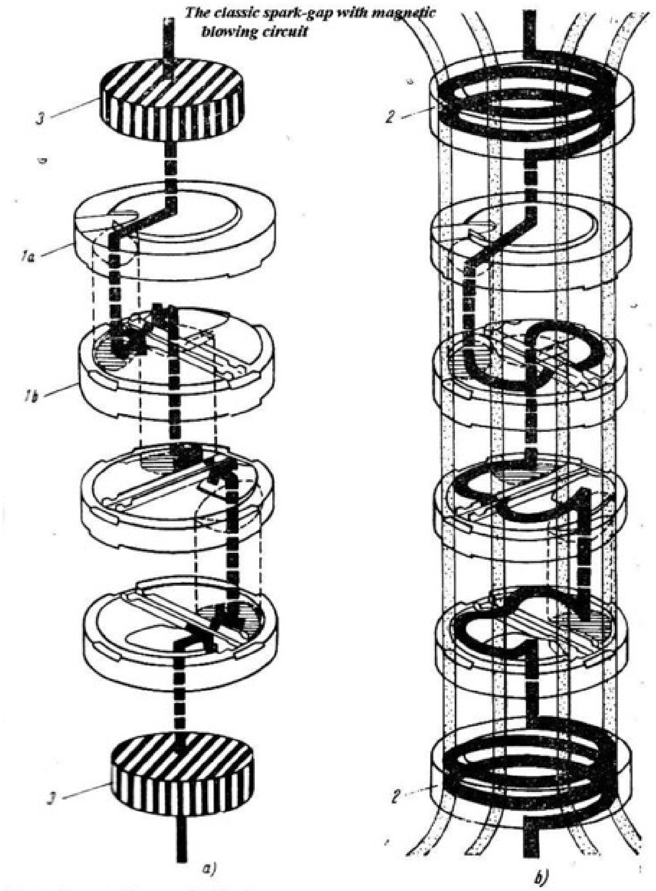
In considering Figure 3, which represents a sort of an installation scheme of the device, the reception of atmospheric electrical current will, as set out above, producing a priming of these currents. This boot is made in launching the system which is double to answer each of the poles, the current batteries 11 through 12 and reels going to the antenna.

This boot will continue until the disposal of electrical current atmosphere is evident by the one or more table lamps L of resistance shown in Figure 5.

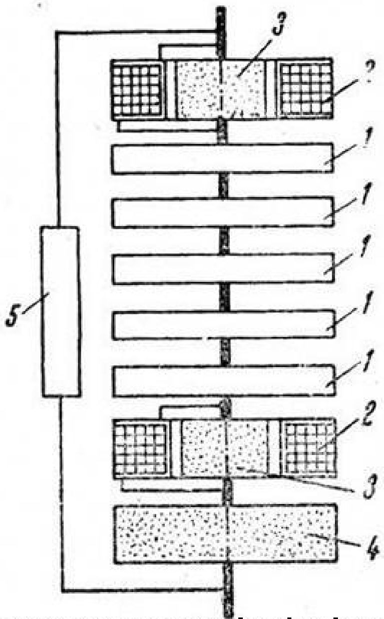
Once the lights illuminate it is advisable to charge the batteries to boot. Natural flow and constant currents will be captured by the regulators , Figure 3; they will regularize in tension and in amperage and then directed to use in table lamps.

It has been said above that regulators R, etc., are intended and designed to automatically eliminate earth surge currents capture and abnormal currents that cannot yet be level but that these regulators could be replaced by devices with the same function.

There is therefore no need to describe in detail and especially the claims. We only specify that these regulators must be proper protection for the purposes described above.



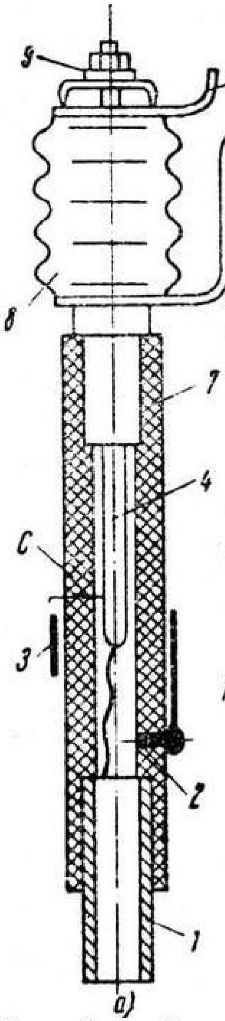
The spark-gap with magnetic blowing :
a,- the initial stage ; the impulse current send in soil through the shunt-resistences 3, because the coils 2 have an impedance too big for the impulse of 10/20 µs ;
the spark-gap 1 has two elements disc-shaped 1a and 1b, the inferior disc have one electrode and the upper disc the other electrode of the spark-gap circuit.
b,- the second stage ; the accompanying current discharge - after the impulse current ;
this accompanying current pass through the coils 2 which produce the magnetic field with the role to extend the electric arc into the slit between insulator discs 1a and 1b ; the thickness of this slit is smaller and smaller in accord with the extension of the electric arc, in this manner producing the magnifing of its electric resistance and finally, the electric arc extinction.

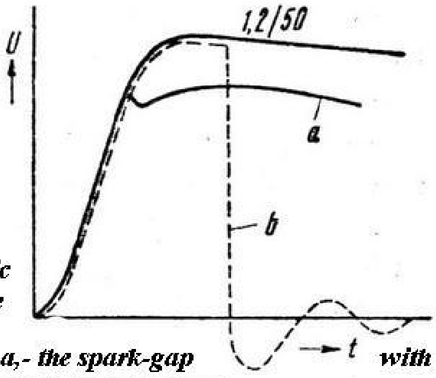


1,- the spark-gap individual devices which work in the manner to extend the electric arc of the accompanying electric current ;
2,- the coils which produce the magnetic field for the magnetic blowing ;
3,- the electric shunt-resistances in parallel connection on the blowing coils, with the role of reducing the current inside this coils
4,- the disc with unlinear resistance ;
5,- electrical resistance for the homogenous distribution of the electric field in all the elements of the spark-gap.

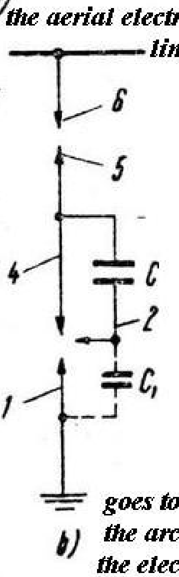
In Jules Guillot scheme, that kind of device could be used for leading the current.

Spark-gap element with circuit for the magnetic blowing of the electric fascicle





a,- the spark-gap with variable resistance ;
b,- the tube spak-gap ;
t - the time



The tube spark-gap has the aerial spark gap with the electrodes 5 and 6 disposed at the insulator 8 extremities ; and one arc-over spark-gap device between the rod 4 and the electrode 1.

At start, the first spark apear in the aerial spark-gap and then, the electric dicharge goes to the gas-producing tube 7, where it makes the arc-over. The local pressure in the gas allow the electric arc extinction, after managing the over electric tension into soil. The capacity C which is created between the external ring 3 and the rod 4 is bigger than the Capacity C_1 between 1 an 2 in that manner, when the overtension apears, the auxiliary spark-gap 1, 2 will start working and then, the main spark-gap 1, 4. In this circuit, the electrode 9 is connected at the aerial electric line and the electrode 1 at the Earth.

In the image above, it is an classic tube spark-gap used for the protection of aerial electric cables. The atmospheric electricity is discharged in soil and lost... The Guillot's inventions used that kind of devices for leading and absorbing of the atmospheric electricity.

DARIDA, Gillbert : "Practical Utilization of Atmospheric Electricity";
(in *The Invention Encyclopedia,* pp. 204-207 ; 1930, Geo. Constantinescu, Ed.) --

Pământul ca și celelalte astre, posedă o electricitate proprie negativă în interior, iar aerul care-l înconjoară este pozitiv. Potențialul sau tensiunea electrică a aerului se mărește pe măsură ce ne ridicăm în înălțime, astfel că putem spune că intensitatea electrică este proporțională cu înălțimea (după lucrările remarcabile ale lui Franklin, Quetelet, Lord Kelvin, Mascart, Joubert și a altor mari savanți fizicieni).

Observațiile făcute recent, au arătat că aerul regiunilor înalte dela 6000—7000 m este foarte încărcat cu electricitate pozitivă, a cărei explicație se datorește frecării fotosferei sau atmosferei terestre, prin învârtirea pământului în jurul soarelui cu mai mult de o sută de mii de km pe oră. Această frecare directă în fluidul eteric ambiant, face ca aerul să se încarce cu electricitate pozitivă prin influență, iar pământul să se încarce negativ.

Intre cele două medii, fluidic (aerul) și (pământul) materie, știința ne spune, că în partea de jos a atmosferei, pe timp frumos un centimetru cub de aer ionizat, conține circa 800 particule cu ioni pozitivi și 680 ioni negativi (electroni).

Pământul se comportă ca un enorm conductor încărcat negativ, respingând electroni și atrăgând ionii pozitivi. Această atracție a ionilor pozitivi determină un curent electric, zis și curent de convențiune. E un fel de bombardament invizibil supus variațiunilor zilei și a sezoanelor, putându-l evalua aproximativ la o densitate mijlocie remarcabilă, dela 3×10^{16} sau a 30 quatrilionime de amper pe cm cub, ceea ce dă pentru întreagă suprafață a pământului un curent formidabil, de 1500 de amperi.

Se pune întrebarea cum un astfel de curent poate să-și întreție mereu același sens? Aceasta este enigma pe care ne-o punem, studiind curenții naturali ai atmosferei noastre, presupunem că poate să fie o legătură a acțiunii emanațiunilor radioactive. Aceste emanațiuni fiind din gaze radioactive grele, se găsesc de obiceiu în mare abundență aproape de pământ ceea ce ne explică marea ionizare observată în general în grote și caverne.

Ionizarea atmosferică poate de asemenea fi produsă în parte, de acțiunea razelor X, foarte pătrunzătoare și de diferite substanțe radioactive închise în subsolul pământului. De asemenea poate să mai fie, ținând seama de acțiunea «Calei Lactee» și de ionizarea luminei solare, foarte bogată în radiațiuni ultraviolete precum și a electronilor emiși direct din radierea căldurii solare de circa 6000 de grade.

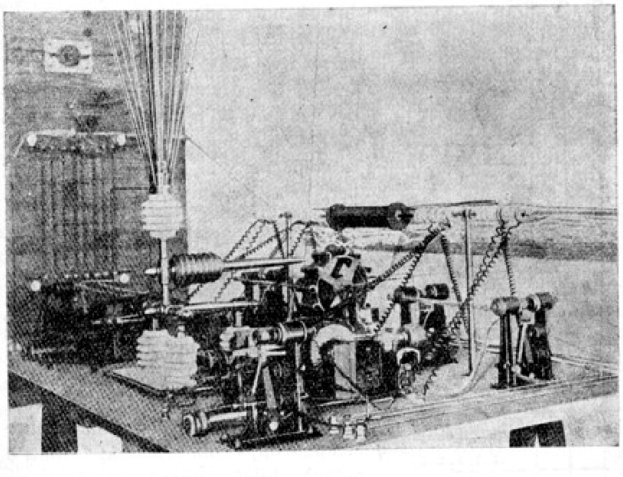


Fig. 108

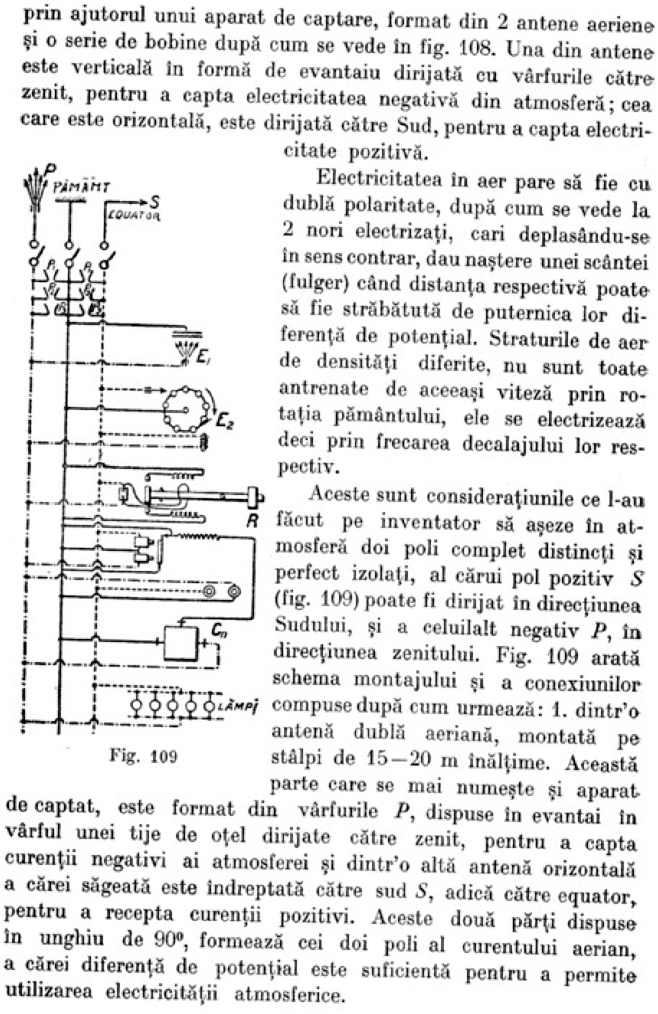
Captarea electricității atmosferice a fost utilizată în Franța prin cabluri aeriene montate pe Mont Blank, iar în Germania prin cabluri susținute de baloane captive.

Sunt mai multe sisteme, vom da pe scurt pe cel mai ingenios procedeu, inventat de ing. Jules Guillot, bazat pe sifonul electric. Procedeul consistă de a pompa direct din atmosferă, electricitate



prin ajutorul unui aparat de captare, format din 2 antene aeriene şi o serie de bobine după cum se vede în fig. 108. Una din antene este verticală în formă de evantaiu dirijată cu vârfurile către zenit, pentru a capta electricitatea negativă din atmosferă; cea care este orizontală, este dirijată către Sud, pentru a capta electricitate pozitivă.

LĂMPI

Fig. 109

Electricitatea în aer pare să fie cu dublă polaritate, după cum se vede la 2 nori electrizaţi, cari deplasându-se în sens contrar, dau naştere unei scântei (fulger) când distanţa respectivă poate să fie străbătută de puternica lor diferenţă de potenţial. Straturile de aer de densităţi diferite, nu sunt toate antrenate de aceeaşi viteză prin rotaţia pământului, ele se electrizează deci prin frecarea decalajului lor respectiv.

Aceste sunt consideraţiunile ce l-au făcut pe inventator să aşeze în atmosferă doi poli complet distincţi şi perfect izolaţi, al cărui pol pozitiv *S* (fig. 109) poate fi dirijat în direcţiunea Sudului, şi a celuilalt negativ *P*, în direcţiunea zenitului. Fig. 109 arată schema montajului şi a conexiunilor compuse după cum urmează: 1. dintr'o antenă dublă aeriană, montată pe stâlpi de 15—20 m înălţime. Această parte care se mai numeşte şi aparat de captat, este format din vârfurile *P*, dispuse în evantai în vârful unei tije de oţel dirijate către zenit, pentru a capta curenţii negativi ai atmosferei şi dintr'o altă antenă orizontală a cărei săgeată este îndreptată către sud *S*, adică către equator, pentru a recepta curenţii pozitivi. Aceste două părţi dispuse în unghiu de 90°, formează cei doi poli al curentului aerian, a cărei diferenţă de potenţial este suficientă pentru a permite utilizarea electricităţii atmosferice.

French Patent # 551,882

Appareil Capteur de Courants Electriques dans L'Atmosphere

BREVET D'INVENTION.

XII. — Instruments de précision, électricité.

5. — Production de l'électricité, moteurs électriques.

N° 551.882

Appareil capteur de courants électriques dans l'atmosphère.

M. Jules GUILLOT résidant en France (Tarn-et-Garonne).

Demandé le 27 septembre 1921, à 15^{h} 20^{m}, à Paris.
Délivré le 15 janvier 1923. — Publié le 16 avril 1923.
[Brevet d'invention dont la délivrance a été ajournée en exécution de l'art. 11 § 7 de la loi du 5 juillet 1844 modifiée par la loi du 7 avril 1902.]

Considérant le globe terrestre comme l'induit d'une dynamo, dont l'éther supraterrestre est l'inducteur, des courants électriques circulent dans l'intervalle c'est-à-dire dans la couche atmosphérique; l'inventeur capte au moyen de l'appareil décrit ci-dessous deux de ces courants parfaitement distincts et élimine les autres.

L'appareil comprend :

1° Le capteur aérien; 2° une série de parafoudres; 3° les régulateurs; 4° un tableau de résistances; 5° les aspirateurs; 6° les témoins.

1° Le capteur aérien monté sur un poteau est composé d'une pointe d'acier aimanté fixée par scellement sur un isolateur porcelaine et cerclée à sa base par une bague de bronze sur laquelle sont vissées 32 aiguilles de fer doux, le tout formant l'antenne d'un pôle. A côté et isolé de la première, formant le 2e pôle, est fixée une pointe d'acier aimanté dans la position horizontale et dirigée vers le sud dont la base coudée à 45° est scellée sur un isolateur porcelaine. Cette pointe est également cerclée d'une bague de cuivre à encoches fig. 1.

2° Une série de 6 parafoudres à cornes entre chaque pôle et la terre et à écartements variés.

3° Un premier régulateur formé d'un appareil absolument semblable au capteur aérien, mais ayant les deux pôles superposés, et, opposé à la pointe verticale, un disque de cuivre relié à la terre. Opposé à la pointe horizontale, une roue à jante d'étain sur laquelle sont soudés alternativement 16 tubes composés eux-mêmes de deux métaux soudés : cuivre-plomb et fer-plomb. Cette roue est reliée à la terre par son pivot fig. 2.

Un deuxième régulateur formé d'appareils à déclanchement automatique au nombre de 3 par pôles et deux basculateurs également par pôles.

4° Un tableau de résistances composé de fils de maillechort en boudins de différentes sections, de tubes en verre contenant des poussières de cuivre, du charbon de cornue et de la fleur de soufre.

5° Les aspirateurs composés d'une boîte en bois sur chaque pôle, contenant un vase de porcelaine dans lequel par couches superposées et isolées au mica est placé du mercure, de l'étain, du charbon, du cuivre et du soufre, le tout traversé par une tige de cuivre.

6° Les témoins composés de lampes à incandescence ordinaires.

RÉSUMÉ.

Par la pointe au zénith et par la pointe au sud nous canalisons deux courants formant les deux pôles. On protège l'ensemble par des parafoudres. On régularise le débit par un régulateur semblable et par des appareils à déclanchement commandant chacun des résistances appropriées de la nature du courant nuisible dont ces appareils sont chargés. Les courants épurés sont conduits aux témoins par des fils de cuivre ordinaire.

N° 565.395

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate.

M. Jules GUILLOT résidant en France (Allier).

Demandé le 6 avril 1923, à 11h 30m, à Paris.
Délivré le 7 novembre 1923. — Publié le 25 janvier 1924.

On sait que la terre, par sa propre constitution, sa rotation et son mouvement dans l'espace, fournit à elle seule l'électricité que l'on utilise et qui est en suspension dans l'atmosphère. Les courants électriques, qui s'échappent de la surface du globe, montent directement dans l'espace où les grandes masses sont accumulées vers l'équateur, par suite de la plus grande périphérie du globe.

Dans l'atmosphère, il y a deux pôles parfaitement distincts, c'est-à-dire que des nuages peuvent être électrisés, soit d'électricité positive ou négative; ceci, tout dans la nature le démontre, sans quoi, il serait difficile d'expliquer la provenance des éclairs qui se produisent entre les nuages et qui ne sont autres que des nuages chargés d'électricité contraire et qui s'amorcent entre eux par un trop grand rapprochement.

L'invention dont il s'agit concerne un dispositif formé d'un ensemble d'appareils aptes à la captation de ces courants atmosphériques.

Jusqu'à ce jour, toutes les recherches faites dans ce but ont été de capter dans l'atmosphère une seule catégorie de courants atmosphériques, c'est-à-dire, qu'on a réuni dans un même système de captation, deux pôles opposés et dont l'effet a été de se détruire ou de s'annuler l'un à l'autre laissant comme quantité que la différence du plus fort au plus faible.

Il sera donc facile de comprendre pourquoi, en considérant les deux pôles d'un courant atmosphérique comme à peu près égaux, il est presque impossible par certains temps de mesurer le potentiel avec la terre, du plus fort sur le plus faible subsistant et qui peut être positif ou négatif, suivant que le plus fort est de l'une ou de l'autre de ces polarités.

C'est sur cette base que toutes les recherches jusqu'à nos jours ont été faites et c'est pourquoi, il faut considérer que par tous les temps, entre les deux pôles captés dans l'atmosphère et non mélangés dans aucun des systèmes de captation, il est possible d'obtenir, en tension et en intensité, une puissance aussi considérable que l'on puisse désirer et qui sera mesurée entre les deux pôles captés séparément et toujours isolés l'un de l'autre jusqu'à leur utilisation.

Suivant l'invention, cette captation se fait par attraction dans l'atmosphère au moyen d'un amorçage des courants électriques, soit positif ou négatif, par une antenne à deux pointes absolument isolées l'une de l'autre, dont l'une tournée vers le zénith attire les couches d'électricité négative, et l'autre, tournée vers le sud, puise vers l'équateur, dans les masses groupées dans cette zone.

Ceci exposé et l'existence des courants électriques atmosphériques étant prouvée, il est

possible de les capter à la condition de disposer d'appareils spéciaux étudiés surtout pour jouer le rôle de régulateurs, attendu que la difficulté persistante rencontrée jusqu'alors pour réaliser la captation incombe aux grandes variations de tensions sous lesquelles les courants atmosphériques se présentent dans l'espace, pour chacun des pôles, et dont l'écoulement dans un poste de captation serait inévitablement funeste.

Le présent brevet sous sa forme de présentation doit donc couvrir, non pas le ou les dispositifs régulateurs qui sont prévus dans le système, car ils peuvent être conçus d'une façon toute différente et donner le même résultat, mais sur l'application raisonnée et le groupement d'appareils fonctionnant automatiquement et intervenant chacun comme relais d'influence variable pour limiter la tension des courants captés dans l'atmosphère à celle choisie pour utilisation.

Ces appareils ont un rôle assez connexe avec celui de trop-pleins sur un réservoir qui acheminent à l'extérieur l'excès de liquide; ici ces régulateurs détournent l'excès de tension des courants à la terre.

On peut encore assimiler ces régulateurs à des filtres car ils ont pour but de détourner du poste d'utilisation, des courants qui ne sont pas encore de nature connue mais que pour simplicité on appellera courants parasites ou anormaux.

Le brevet portera aussi sur le système de régulation des courants, appliqué à chacun des pôles, car il est reconnu que la forme et la tension des courants aux deux pôles ne sont pas équivalentes.

Le mode de captation par antenne spéciale à deux pointes orientées dans l'atmosphère, comme il sera indiqué ci-après, avec amorçage préalable pour l'écoulement des courants atmosphériques est aussi d'une grande importance.

Enfin la réception des courants atmosphériques se fait à l'endroit même de l'installation du poste; celui-ci peut être prévu en un lieu quelconque sans nécessiter d'altitude particulière, comme cela a été tenté dans des essais préconçus.

Sur les dessins ci-annexés auxquels on se réfère

La fig. 1 représente en élévation et en coupe partielle l'antenne seule, à deux pointes, surmontant un poteau d'élévation;

La fig. 2 est le plan de l'une des pointes, celle horizontale:

La fig. 3 montre schématiquement le tableau sur lequel sont montés les divers appareils ou accessoires qui jouent le rôle de régulateurs des tensions de courants.

La fig. 4 est un schéma de parafoudre, et

La fig. 5 un tableau de résistances.

Le dispositif nécessaire à la captation des courants atmosphériques est formé comme suit :

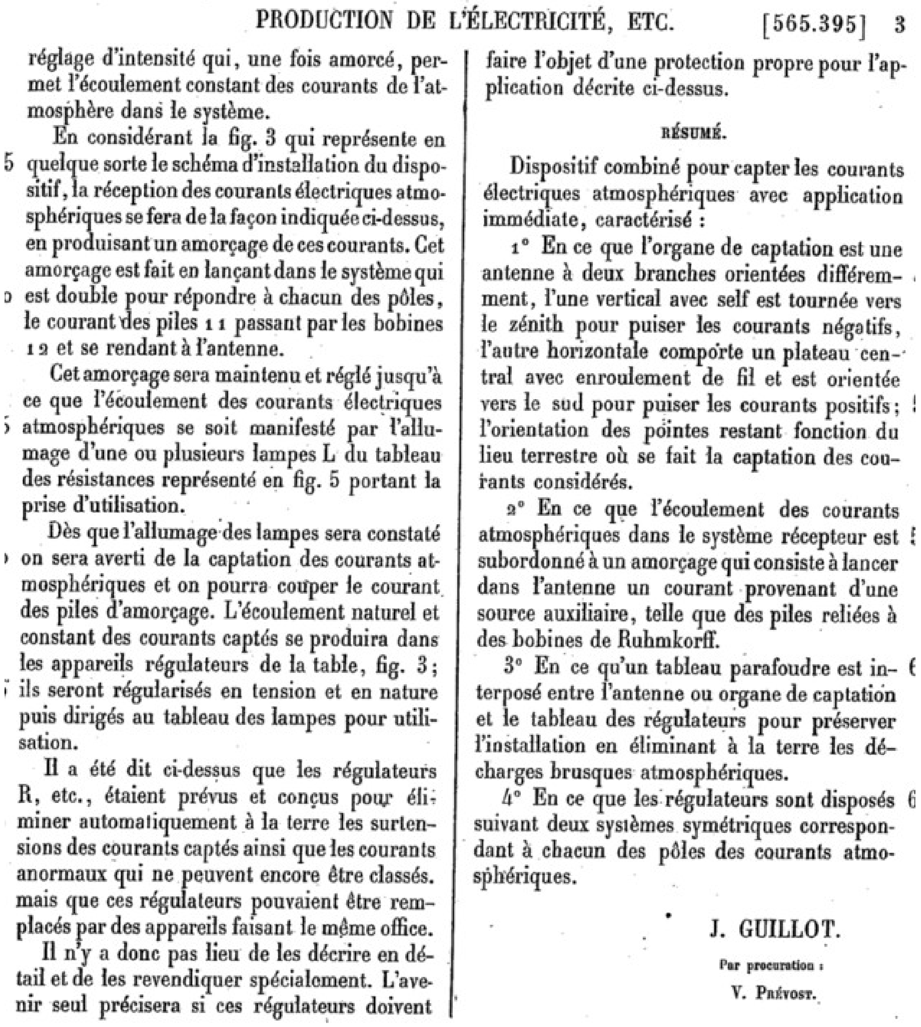
1° D'une antenne, fig. 1, formée de deux pointes dont l'une 1 est en acier, supportée par une bague de bronze 2 entourée d'une spirale 3 formant self; cette pointe est tournée vers le zénith pour attirer les couches d'électricité négative; l'autre pointe 4 comporte un cadre 5 de huit branches supportant des spirales de cuivre 6 et est tournée vers le sud pour puiser vers l'équateur dans les masses groupées dans cette zone. Pour l'utilisation de cette antenne il suffira qu'elle soit portée par un mât ou poteau de hauteur un peu supérieure à celle des habitations environnantes.

2° D'un tableau de parafoudre, fig. 4, formé de cornes de cuivre 7 servant à absorber les tros grosses décharges atmosphériques que par certains temps, il serait dangereux de laisser circuler dans les appareils régulateurs.

3° D'une table de deux systèmes symétriques de régulateurs, fig. 3, un pour chaque pôle, qui permet d'obtenir une régularisation assez grande dans les tensions des courants en absorbant automatiquement les surtensions dépassant la tension choisie pour l'utilisation désirée. Ces régulateurs sont représentés sur le dessin par les références R, R^1, R^2, R^3, R^4.

4° D'un tableau de résistance en communication avec les régulateurs, ces résistances sont formées de spirales de maillechor 8, de tubes 9 de verre remplis de poussière fine de charbon de cornue, de poudre d'aluminium, de soufre et de poussière fine de cuivre; enfin, deux appareils spéciaux 10 formant transformateurs et constitués de couches de métaux absorbant certains courants nuisibles ou anormaux.

5° D'une source auxiliaire d'énergie formée de piles 11 et de bobines Ruhmkorff 12 permettant d'obtenir dans l'antenne une attraction suffisante au moyen d'un dispositif de



réglage d'intensité qui, une fois amorcé, permet l'écoulement constant des courants de l'atmosphère dans le système.

En considérant la fig. 3 qui représente en quelque sorte le schéma d'installation du dispositif, la réception des courants électriques atmosphériques se fera de la façon indiquée ci-dessus, en produisant un amorçage de ces courants. Cet amorçage est fait en lançant dans le système qui est double pour répondre à chacun des pôles, le courant des piles 11 passant par les bobines 12 et se rendant à l'antenne.

Cet amorçage sera maintenu et réglé jusqu'à ce que l'écoulement des courants électriques atmosphériques se soit manifesté par l'allumage d'une ou plusieurs lampes L du tableau des résistances représenté en fig. 5 portant la prise d'utilisation.

Dès que l'allumage des lampes sera constaté on sera averti de la captation des courants atmosphériques et on pourra couper le courant des piles d'amorçage. L'écoulement naturel et constant des courants captés se produira dans les appareils régulateurs de la table, fig. 3; ils seront régularisés en tension et en nature puis dirigés au tableau des lampes pour utilisation.

Il a été dit ci-dessus que les régulateurs R, etc., étaient prévus et conçus pour éliminer automatiquement à la terre les surtensions des courants captés ainsi que les courants anormaux qui ne peuvent encore être classés. mais que ces régulateurs pouvaient être remplacés par des appareils faisant le même office. Il n'y a donc pas lieu de les décrire en détail et de les revendiquer spécialement. L'avenir seul précisera si ces régulateurs doivent faire l'objet d'une protection propre pour l'application décrite ci-dessus.

RÉSUMÉ.

Dispositif combiné pour capter les courants électriques atmosphériques avec application immédiate, caractérisé :

1° En ce que l'organe de captation est une antenne à deux branches orientées différemment, l'une vertical avec self est tournée vers le zénith pour puiser les courants négatifs, l'autre horizontale comporte un plateau central avec enroulement de fil et est orientée vers le sud pour puiser les courants positifs; l'orientation des pointes restant fonction du lieu terrestre où se fait la captation des courants considérés.

2° En ce que l'écoulement des courants atmosphériques dans le système récepteur est subordonné à un amorçage qui consiste à lancer dans l'antenne un courant provenant d'une source auxiliaire, telle que des piles reliées à des bobines de Ruhmkorff.

3° En ce qu'un tableau parafoudre est interposé entre l'antenne ou organe de captation et le tableau des régulateurs pour préserver l'installation en éliminant à la terre les décharges brusques atmosphériques.

4° En ce que les régulateurs sont disposés suivant deux systèmes symétriques correspondant à chacun des pôles des courants atmosphériques.

J. GUILLOT.

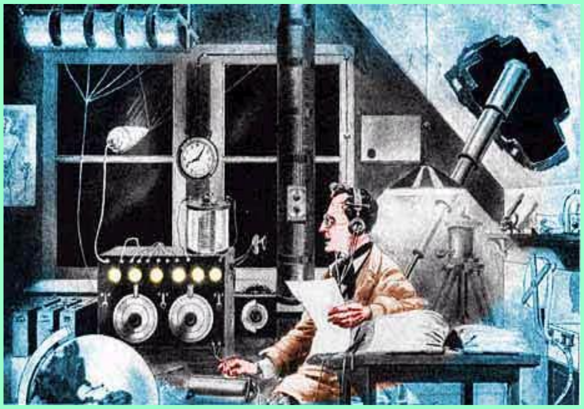
"CRYSTAL RADIOS AND SPARK GAP TRANSMITTERS"

"Built to order by, AIRWAVE EXPLORER LABS"



These are a sample of some of the Crystal Radios I build. My Father and Uncle had a shop in Jackson, Michigan from 1919 until 1929. They designed and built custom Crystal Radios to sell. I am attempting to relive those Golden Times & Days of Radio by following in their footsteps. I have been a Ham Radio Operator for over 65 years now. This has given me the experience to hand build these radios. I am trying to follow the schematics and designs my Father used. I use as many vintage parts as I can. I try to always use old tongue and groove, box joint, finger joint and dove tail boxes. I test and "Pot" my own crystals. I can build you a radio per your specifications or mine. Using your box or mine. These spark gap transmitters are meant to be for display. Not to be connected to an antenna or ground and operated. It is illegal to operate a spark gap transmitter. I accept, PAY PAL, checks, or Money Orders. So light up that old oil lamp, put on your headphones and travel back in time to the Golden Age of Radio.

(57) ABSTRACT

Systems and methods for processing salt water and/or solutions containing salt water with RF energy. Exemplary systems and methods may use RF energy to combust salt water, to produce hydrogen from salt water or solutions containing salt water, to volatilize a secondary fuel present in solutions containing salt water, to produce and combust hydrogen obtained from salt water or solutions containing salt water, to volatilize and combust secondary fuel sources present in solutions containing salt water, to desalinate seawater, and/or to carry out the electrolysis of water are presented. An exemplary system may comprise a reservoir for containing a salt water solution or salt water mixture; a reaction chamber having an inlet; a feed line operatively connecting the reservoir to the inlet of the reaction chamber; an RF transmitter having an RF generator in circuit communication with a transmission head, the RF generator capable of generating an RF signal absorbable by the salt water solution or the salt water mixture having a frequency for transmission via the transmission head; and an RF receiver; wherein the reaction chamber is positioned such that some of the salt water solution or salt water mixture is positioned between the RF transmission head and the RF receiver.

RF SYSTEMS AND METHODS FOR PROCESSING SALT WATER

RELATED CASES

[0001] This application claims priority to, and any other benefit of, U.S. Provisional Patent Application No. 61/033,962, filed Mar. 5, 2008 and entitled "RF SYSTEMS AND METHODS FOR PROCESSING MATERIALS," which is herein incorporated by reference. This case is related to U.S. patent application Ser. No. 11/939,225 of Kanzius, filed Nov. 13, 2007, and entitled RF SYSTEMS AND METHODS FOR PROCESSING SALT WATER, (Attorney Docket 32403/04004); PCT Patent Application Serial No. PCT/U.S.07/84541 of Kanzius and Roy, filed Nov. 13, 2007, and entitled RF SYSTEMS AND METHODS FOR PROCESSING SALT WATER, (Attorney Docket 32403/04003); U.S. Provisional Patent Application Ser. No. 60/865,530 of Kanzius, filed Nov. 13, 2006, and entitled RF SYSTEM AND METHODS FOR PROCESSING SALT WATER (Attorney Docket 30064/04004) ("the '530 application"); U.S. Provisional Patent Application Ser. No. 60/938,613. of Kanzius, filed May 17, 2007, and entitled RF SYSTEM AND METHODS FOR PROCESSING SALT WATER II (Attorney Docket 30064/04008) ("the '613 application"); U.S. Provisional Patent Application Ser. No. 60/953,829 of Kanzius, filed Aug. 3, 2007, entitled RF SYSTEM AND METHODS FOR PROCESSING SALT WATER III (Attorney Docket 30064/04009); U.S. patent application Ser. No. 12/036,731 of Kanzius, filed on Feb. 25, 2008, and entitled FIELD GENERATOR FOR TARGETED CELL ABLATION (Attorney Docket 30274/04034); and U.S. Provisional Patent Application Ser. No. 60/915,345 of Kanzius, filed on May 1, 2007, and entitled FIELD GENERATOR FOR TARGETED CELL ABLATION (Attorney Docket 30274/04036), the entire disclosures of which, including all appendices, diagrams, figures, and photographs of which, are hereby incorporated by reference in their entireties.

FIELD OF THE INVENTION

[0002] The present invention relates to systems and methods for processing water utilizing radio frequency (RF) energy, such as, for example, RF systems and methods for combustion of salt water and/or solutions containing salt water, RF systems and methods for desalinating seawater, RF systems and methods for heating seawater, salt water, and/or solutions containing salt water, RF systems and methods for generating steam, RF systems and methods for volatilizing secondary fuels, RF systems and methods for the electrolysis of salt water and salt water mixtures, RF systems and methods for producing hydrogen from salt water and/or solutions containing salt water, RF systems and methods for combustion of volatiles produced from solutions containing salt water, and/or RF systems and methods for combustion of hydrogen produced from salt water and/or solutions containing salt water.

BACKGROUND OF THE INVENTION

[0003] Hydrogen gas is combustible and is therefore a potentially viable fuel source particularly for use in internal combustion engines. Water can be a source of hydrogen gas and unlike crude oil, which is used to produce gasoline, water and particularly seawater has an advantage over crude oil in that it is present on earth in great abundance. Furthermore, the burning of hydrogen produces water, an environmentally clean byproduct. Many other volatile organic compounds, such as ethanol for example, are also combustible and so they too are potentially viable fuel sources for use in internal combustion engines. Likewise, ethanol has an advantage over crude oil in that ethanol can be synthesized from fermentation of corn, sugar cane or other agricultural products and it is therefore a renewable resource, while by contrast crude oil is not.

BRIEF DESCRIPTION OF THE DRAWINGS

[0004] FIGS. **1-7** are high-level block diagrams of exemplary RF systems for RF processing of salt water and/or solutions containing salt water, such as combusting salt water or solutions containing salt water, generating steam from salt water, producing and collecting hydrogen from salt water or solutions containing salt water, and desalinating seawater;

[0005] FIGS. **8**A-**8**C, **9**A-**9**C are various views of exemplary RF transmission and RF reception heads;

[0006] FIGS. **10-12**, **16**, and **16***a* are schematic diagrams of exemplary RF circuits for exemplary RF systems for RF processing of salt water and/or solutions containing salt water, such as combusting salt water or solutions containing salt water, generating steam from salt water, producing and collecting hydrogen from salt water or solutions containing salt water, and desalinating seawater;

[0007] FIGS. **13-15** are top, top/side perspective, and side views of an exemplary RF coupling circuit for exemplary RF systems for RF processing of salt water and/or solutions containing salt water, such as combusting salt water or solutions containing salt water, generating steam from salt water, producing and collecting hydrogen from salt water or solutions containing salt water, and desalinating seawater;

[0008] FIG. **17** is a medium-level flowchart of an exemplary embodiment of an RF methodology for producing and collecting hydrogen gas from salt water and solutions containing salt water;

[0009] FIGS. **18**(*a*) and **18**(*b*) are medium level flow charts of exemplary embodiments of an RF methodology for producing and combusting hydrogen gas from salt water and for producing and combusting hydrogen gas and producing and combusting other volatiles from solutions containing salt water;

[0010] FIGS. **19**(*a*) and **19**(*b*) are medium level flow charts of exemplary embodiments of an RF methodology for producing and combusting hydrogen gas from salt water and for producing and combusting hydrogen gas and producing and combusting other volatiles from solutions containing salt water, and transferring the chemical energy generated by the combustion of the hydrogen gas and other volatiles into mechanical energy capable of moving a piston;

[0011] FIG. **20** is a medium level flow chart of an exemplary embodiment of an RF methodology for desalinating seawater;

[0012] FIG. **21** is a medium level flow chart of an exemplary embodiment of an RF methodology for carrying out the electrolysis of water;

[0013] FIG. **22** is a schematic illustration showing exemplary transmission and reception enclosures with their top walls removed;

[0014] FIG. **23** is a high-level flowchart showing an exemplary method of combusting salt water and solutions containing salt water with RF energy;

[0015] FIG. **24** is a schematic illustration showing an exemplary sealed transmission enclosure which may be suitable for lowering into the ground; and

[0016] FIGS. **25**-**26** are medium level flowcharts of exemplary embodiments of an RF methodology for combusting gas generated from a liquid by a transmitted RF signal.

[0017] FIGS. **27**, **28**, **30** and **34** are photographs showing combustion of the gas product generated by the electromagnetic dissociation of water in accordance with this invention.

[0018] FIGS. **29**, **31**, **32** and **35** are spectra of selected samples subjected to RF irradiation according to this invention.

[0019] FIG. **33** is a photograph showing that a salt water droplet self ignites when dropped into an RF field according to the technology of this invention.

SUMMARY

[0020] Systems are presented for using RF energy to combust salt water and/or various solutions containing salt water, to produce hydrogen from salt water, to produce volatiles from solutions containing salt water, to desalinate seawater, and/or to carry out the electrolysis of water. An exemplary system may comprise a reservoir for containing salt water that is a mixture comprising water and salt, the salt water having an effective amount of salt dissolved in the water; a reaction chamber having an inlet and an outlet; a feed line operatively connecting the reservoir to the inlet of the reaction chamber; an RF transmitter having an RF generator in circuit communication with a transmission head, the RF generator capable of generating an RF signal at least partially absorbable by the salt water having at least one frequency for transmission via the transmission head; and an RF receiver; wherein the reaction chamber is positioned such that at least a portion of the reaction chamber is between the RF transmission head and the RF receiver. Other exemplary systems may comprise a reservoir for containing a solution that is a mixture of water and salt and optionally containing (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof.

[0021] Similarly, methods are presented for using RF energy to combust salt water and solutions containing salt water, to desalinate seawater, to produce hydrogen from salt water and solutions containing salt water, and/or to carry out the electrolysis of salt water. An exemplary method may comprise providing salt water comprising a mixture of water and at least one salt; or a salt water solution comprising a mixture of water and at least one salt and optionally containing (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof; the salt water or salt water solution having an effective amount of the salt dissolved in the water; providing an RF transmitter having an RF generator in circuit communication with a transmission head, the RF generator capable of generating an RF signal at least partially absorbable by the salt water or salt water component of the solution containing salt water and having at least one frequency for transmission via the transmission head; arranging the transmission head near the salt water or solution containing salt water such that the RF signal transmitted via the transmission head interacts with at least some of the salt water; and transmitting the RF signal via the transmission head for a time sufficient to combust the salt water or to heat the solution containing salt water to volatilize and to combust a secondary fuel source that may be optionally present. If hydrogen gas is created from the salt water or the solution containing salt water by the RF signal, the RF signal may also be transmitted via the transmission head sufficient to combust the hydrogen gas so produced.

DETAILED DESCRIPTION

[0022] In the accompanying drawings which are incorporated in and constitute a part of the specification, exemplary embodiments of the invention are illustrated, which, together with a general description of the invention given above, and the detailed description given below, serve to example principles of the invention.

General Terms

[0023] "Additive" as used herein is a chemical compound having solubility, miscibility, or compatibility with various solutions of salt water (including sea water, salt water, or solutions containing salt water and optionally containing at least one secondary fuel) that furthermore is capable of altering the responsiveness of the various solutions of salt water to stimulation by RF energy.

[0024] "Circuit communication" as used herein is used to indicate a communicative relationship between devices. Direct electrical, optical, and electromagnetic connections and indirect electrical, optical, and electromagnetic connections are examples of circuit communication. Two devices are in circuit communication if a signal from one is received by the other, regardless of whether the signal is modified by some other device. For example, two devices separated by one or more of the following—transformers, optoisolators, digital or analog buffers, analog integrators, other electronic circuitry, fiber optic transceivers, or even satellites—are in circuit communication if a signal from one reaches the other, even though the signal is modified by the intermediate device (s). As a final example, two devices not directly connected to each other (e.g. keyboard and memory), but both capable of interfacing with a third device, (e.g., a CPU), are in circuit communication.

[0025] "Combustion" as used herein indicates a process that rapidly produces heat and light (perhaps caused by a rapid chemical change and with or without "burning" or "oxidation" in the classic sense). Salt water and solutions containing salt water respond to RF energy in many of the various systems and methods taught herein with rapid heating and rapid generation of light, which may be visible, UV, IR, etc. This is considered "combustion" herein, even though it may or may not be "burning" in the classic sense. "Combustion" herein also is used to indicate more typical incendiary "combustion," i.e., the process of burning in which a rapid chemical change occurs that produces heat and light, which includes burning in the classical sense of the products produced from salt water reacting with RF. For example, when hydrogen is combusted or burned in air the hydrogen is chemically oxidized into water and undergoes such a rapid reaction that a flame is produced and the water is discharged in the form of steam.

[0026] "Desalinate" as used herein is used to indicate the process of removing salt and other chemicals from water. For example, when desalination of seawater is carried out through heating, e.g., boiling, steam is produced and collected. When the collected steam is subsequently condensed back into a liquid, pure water is obtained free of any salt or minerals. "Electrolysis" as used herein is used to indicate the process of applying energy to water in order to decompose the water into its constituent elements hydrogen and oxygen. Energy can be applied in the form of either electrical energy, as for example in the application of an electric current, or in the form of heat energy.

[0027] "Operatively connected" or "operatively connecting" as used herein is used to indicate that a functional connection (e.g., a mechanical or physical connection or an electrical or optical or electromagnetic or magnetic connection) exists between the components of a system.

[0028] "Salt water" as used herein is used to indicate a mixture comprising water and salt, the salt water having an effective amount of salt dissolved in the water. "Solution containing salt water" and "salt water solutions" are used interchangeably and as used herein indicate a mixture comprising salt water and optionally containing one or more of the following: (i) at least one additive, (ii) at least one secondary fuel, or (iii) mixtures of both. Hence, a solution containing salt water may comprise only salt water. "Salt water mixture" as used herein is used to indicate a mixture containing salt water that is used in conducting electrolysis with the various systems and methods taught herein.

[0029] "Secondary fuel" as used herein is used to indicate combustible organic compounds that can be made volatile and that have solubility, miscibility, or compatibility with various salt water solutions (including salt water, sea water, or salt water solutions containing salt water and optionally containing at least one additive). As used herein, a secondary fuel may be the only substance that is combusting; thus, use of the term secondary fuel does not necessary require that there is a primary fuel also combusting. Salt and salt solutions may be used to increase the combustion of secondary fuels without the salt or salt solution also combusting.

Systems

[0030] Referring to the drawings and to FIGS. **1**-**16**A, various different views of exemplary systems and system components are shown. It is believed that these systems and components may be used with virtually all the various RF absorption enhancers and virtually all the various methods discussed herein.

[0031] The exemplary systems of FIGS. **1**-**4** include an RF generator **102** in circuit communication with a transmission head **104** for transmitting through a reaction chamber **106** an RF signal **108** generated by the RF generator **102** and transmitted by the transmitter head **104**. The reaction chamber **106** may be open or closed, depending on the specific application. The reaction chamber may be, for example, a vessel or a cylinder with an associated piston.

FIG. 1

[0032] Referring to FIG. **1**, there is shown a first exemplary embodiment of an RF system **100** that uses an RF signal **108** to process solutions containing salt water **110** in the reaction chamber **106**. For example, the RF signal **108** may combust the solution containing salt water **110**. As another example, the RF signal **108** may heat the solution containing salt water **110** for further processing, e.g., steam collection and condensing to desalinate a solution containing salt water **110**. As yet another example, the RF signal **108** may produce hydrogen from the solution containing salt water **110** or the RF signal may heat the solution containing salt water and volatilize any secondary fuel that may be optionally contained in the solution. The hydrogen produced as well as any volatilized secondary fuel optionally present may be collected as a gas and stored for various uses, e.g., stored for use as a fuel. Alternative, the hydrogen or any volatilized secondary fuel or both may be combusted in the reaction chamber **106**. Exemplary system **100** comprises an RF generator **102** in circuit communication with a transmission head **104**. A reaction chamber **106** is positioned such that at least a portion of the reaction chamber **106** is RF coupled to the transmission head **104**. In exemplary system **100**, the RF generator **102** communicates an RF signal for transmission to the transmission head **104**. The RF signal **108** transmitted by the transmission head **104** passes through at least a portion of the reaction chamber **106**. A solution containing salt water (and also a solution optionally containing (i) at least one additive, (ii) at least one secondary fuel, or (iii) mixtures thereof) **110** contained within the reaction chamber **106** is positioned such that the solution containing salt water **110** (and in particular the salt water component of the solution) absorbs at least some of the RF signal **108**. Optionally, the RF generator **102** may be controlled adjusting the frequency and/or power and/or envelope, etc. of the generated RF signal and/or may have a mode in which an RF signal at a predetermined frequency and power are transmitted via transmission head **104**. In addition, optionally, the RF generator **102** provides an RF signal **108** with variable amplitudes, pulsed amplitudes, multiple frequencies, etc.

[0033] The solution containing salt water **110** absorbs energy as the RF signal **108** travels through the reaction chamber **106**. The more energy that is absorbed by the salt water component of the solution containing salt water **110** the higher the temperature increase in the area which leads to water decomposition and hydrogen production, and in instances where the solution containing salt water **110** also contains a secondary fuel, this may also lead to volatization and to combustion of the secondary fuel instead of or in addition to decomposition of the salt water and hydrogen production. As even more energy is absorbed by the salt water component of the solution containing salt water **110**, combustion of the hydrogen that is being produced eventually occurs. The rate of energy absorption by the solution containing salt water **110** can be increased by increasing the RF signal **108** strength, which increases the amount of energy traveling through the reaction chamber **106**. Other means of increasing the rate of energy absorption may include but are not limited to concentrating the signal on a localized area of the solution containing salt water **110**, or further mixing with the solution containing salt water at least one additive that is appropriately selected from various chemical species to be capable of altering the rate of energy absorption of the solution containing salt water **110** and as a result may be able to increase the rate of energy absorption by the solution containing salt water **110**. Examples of additives that it is believed may be useful in this regard include surfactants, chemical species that form azeotropic mixtures with water, and chemical species that alter the freezing point of water.

FIGS. 2-4

[0034] As shown in FIGS. **2**-**4**, exemplary systems may also include a receiver head **112** and an associated current path **114** to permit the RF signal **108** to be coupled through the reaction chamber **106**. The systems **200**, **300**, **400** also use an RF signal **108** to process solutions **110** in the reaction chamber **106**. For example, the RF signal **108** may combust the solution containing salt water **110**. As another example, the

RF signal **108** may heat the salt water component of the solution containing salt water **110** in preparation for further processing (e.g.: in instances where the solution containing salt water **110** is salt water alone, steam collection and condensing to desalinate the salt water; in instances where the solution containing salt water contains a secondary fuel, the volatization of the secondary fuel). As yet another example, the RF signal **108** may produce hydrogen from or may volatilize a secondary fuel contained within the solution containing salt water **110** and the hydrogen or the volatilized secondary fuel or both may be collected as a gas and stored for various uses, e.g., stored for use as a fuel. In the alternative, the hydrogen produced or the volatilized secondary fuel or both may be combusted in the reaction chamber **106**.

[0035] Referring to FIG. **2**, the exemplary system **200** has a transmission head **104** and receiver head **112** arranged proximate to and on either side at least a portion of the reaction chamber **106**. This allows at least a portion of the solution containing salt water **110** in the reaction chamber **106** to be exposed to the RF signal **108** transmitted by the transmission head **104**. Some portion of the RF system may be tuned so that the receiver head **112** receives at least a portion of the RF signal **108** transmitted via the transmission head **104**. As a result, the receiver head **112** receives the RF signal **108** that is transmitted via the transmission head **104**.

[0036] The heads **104**, **112** may each or both have associated tuning circuitry such as pi-networks or tunable pi-networks, to increase throughput and generate a voltage in the area of the reaction chamber **106** and in the solution containing salt water salt **110** contained within. Thus, as shown in FIG. **3**, the transmission head **104** may have an associated tuning circuit **116** in circuit communication between the RF generator **102** and the transmission head **104**. Additionally, or in the alternative, as shown in FIG. **3**, the current path **114** may comprise the receiver head **112** being grounded.

[0037] Referring to FIG. **3**, the transmission head **104** and receiver head **112** may be insulated from direct contact with the reaction chamber **106**. The transmission head **104** and receiver head **112** may be insulated by means of an air gap **118**. An optional means of insulating the transmission head **104** and receiver head **112** from the reaction chamber **106** is shown in FIG. **4**. The exemplary system **400** includes inserting an insulating layer or material **410** such as, for example, Teflon® between the heads **104**, **112** and the reaction chamber **106**. Other optional means include providing an insulation area on the heads **104**, **112**, and allowing the heads to be put in direct contact with the reaction chamber **106**. The transmission head **104** and the receiver head **112**, described in more detail below, may include one or more plates of electrically conductive material.

[0038] One optional method of inducing a higher temperature in the solution containing salt water **110** includes using a receiver head **112** that is larger than the transmission head **104** (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature, perhaps because of the use of a high-Q resonant circuit described in more detail below). For example, a single 6" circular copper plate may be used on the Tx side and a single square 9.5" copper plate may be used on the Rx side. Optionally, an RF absorption enhancer may be added to the solution containing salt water **110**. An RF absorption enhancer is any means or method of increasing the tendency of the solution containing salt water **110** to absorb more energy from the RF signal that the salt water component of the solution containing salt water would otherwise absorb. Suitable RF absorption enhancers include, for example, suspended particles of electrically conductive material, such as metals, e.g., iron, various combination of metals, e.g., iron and other metals, or magnetic particles. The many types of RF absorption enhancers are discussed in greater detail below.

[0039] The RF generator **102** may be any suitable RF signal generator, generating an RF signal at any one or more of the RF frequencies or frequency ranges discussed herein. The RF signal **108** generated by the RF generator **102** and transmitted by the transmission head **104** may have a fundamental frequency in the HF range or the VHF range or an RF signal at some other fundamental frequency. The RF signal **108** may be a signal having one or more fundamental frequencies in the range(s) of 1-2 MHz, and/or 2-3 MHz, and/or 3-4 MHz, and/or 4-5 MHz, and/or 5-6 MHz, and/or 6-7 MHz, and/or 7-8 MHz, and/or 8-9 MHz, and/or 9-10 MHz, and/or 10-11 MHz, and/or 11-12 MHz, or 12-13 MHz, or 13-14 MHz, or 14-15 MHz. The RF signal **108** may have a fundamental frequency at 13.56 MHz. The RF generator **102** may be an ENI Model No. OEM-12B (Part No. OEM-12B-07) RF generator, which is marked with U.S. Pat. No. 5,323,329 and is known to be used to generate a 13.56 MHz RF signal for etching systems. Among other things, the ENI OEM-12B RF generator has an RF power on/off switch to switch a high-power (0-1250 Watt) RF signal, has an RF power output adjust to adjust the power of the signal generated, and has an RF power meter to measure the power of the RF signal being generated that can be switched to select either forward or reverse power metering. The power meter in reverse mode can be used to calibrate a tuning circuit, as explained above, by adjusting any variable components of the tuning circuit until minimum power is reflected back to the power meter (minimum VSWR). The ENI OEM-12B RF generator may be cooled by a Thermo Neslab Merlin Series M33 recirculating process chiller. A at 13.56 MHz RF signal from the ENI OEM-12B RF generator having a power of about 800-1000 Watts will combust salt water. In the alternative, the RF generator may be a commercial transmitter, e.g., the transmitter portion of a YAESU brand FT-1000MP Mark-V transceiver. An RF signal can be generated at about 13.56 MHz (one of the FCC-authorized frequencies for ISM equipment) by the transmitter portion of a YAESU brand FT-1000MP Mark-V transceiver by clipping certain blocking components as known to those skilled in the art. The RF generator and transmission head may have associated antenna tuner circuitry (not shown) in circuit communication therewith or integral therewith, e.g., automatic or manual antenna tuner circuitry, to adjust to the impedance of transmission head and the reaction chamber (and a receiver, if any). The transmitter portion of a YAESU brand FT-1000MP Mark-V transceiver has such integral antenna tuner circuitry (pressing a "Tune" button causes the unit to automatically adjust to the load presented to the RF generator portion). The RF generator and transmission head may have associated antenna tuner circuitry (not shown) in circuit communication therewith or integral therewith, e.g., automatic or manual antenna tuner circuitry, to adjust to the combined impedance of the reaction chamber and the receiver and compensate for changes therein. The transmitter portion of a YAESU brand FT-1000MP Mark-V transceiver has such integral antenna tuner circuitry. Various configurations for the transmission head and reception head are possible, as exemplified herein.

FIGS. 5-6

[0040] The transmission head **104** may be any of a number of different transmitter head configurations, such as an electrically conductive plate having a coaxial coil in circuit communication therewith. In the alternative, as exemplified by FIG. **5**, the transmission head **104** may comprise (or consist of) an electrically conductive plate **502** (e.g., a 6" diameter, flat, planar plate made of 0.020" stainless steel) without a corresponding coil. The transmission plate **502** may be circular and may be sized depending on the size of the target area and the desired voltage field generated by the plate. Similarly, as exemplified by FIG. **6**, the receiver head **112** may comprise (or consist of) an electrically conductive plate **602** (e.g., a 6" diameter, flat, planar plate made of 0.020" stainless steel) without a corresponding coil. The reception plate **602** may be circular and may be sized depending on the size of the target area and the desired voltage field generated by the plate. The reception plate **602** may be sized substantially smaller or substantially larger than the transmission plate **502** to change the field generated in the reaction chamber **106** by the coupled RF signal **108**. In the alternative, either the reception plate **602** or the transmission plate **502** (which includes both of them) may be parabolic plates with their convex side facing the target area (not shown). The plates may be made of copper (e.g., 0.090" copper plate) instead of stainless steel.

FIG. 7-9

[0041] In the alternative, the transmission head **104** or receiver head **112** may each or both be comprised of a series of spaced, stacked electrically conductive plates. The spaced, stacked electrically conductive plates may be coaxial, circular plates and may have sequentially decreasing diameters. FIG. **7** shows an exemplary system **700** wherein the receiver head **112** comprising spaced, stacked, electrically conductive, coaxial, and circular plates that have sequentially decreasing diameters. The plates of exemplary receiver head **800** may be constructed as described in FIGS. **8**A-**8**C (e.g., sized as shown with an Aluminum base) and may be insulated from each other as described in FIGS. **8**A-**8**C. The plates may be made of copper (e.g., 0.090" copper plate) instead of stainless steel.

[0042] Similarly, the transmission head **104** may comprise a series of spaced, stacked electrically conductive plates. The spaced, stacked electrically conductive plates may be coaxial, circular plates and may have sequentially decreasing diameters. FIGS. **9**A-**9**C show an exemplary transmission head **900** comprising spaced, stacked, electrically conductive, coaxial, and circular plates that have sequentially decreasing diameters. The plates of exemplary transmission head **900** may be constructed as described in FIGS. **9**A-**9**C (e.g., sized as shown with a Teflon base) and may be insulated from each other as described in FIGS. **9**A-**9**C. In the alternative, plates of exemplary receiver head **800** and/or the plates of exemplary transmission head **900** may be in circuit communication with each other, e.g., directly electrically coupled in their spaced configuration with electrically conductive fasteners. The plates may be made of copper (e.g., 0.090" copper plate) instead of stainless steel. A transmission head **900** with electrically insulated plates may be used with a receiver head **800** with electrically connected plates, and vice versa.

FIGS. 10-16

[0043] The tuning circuit **116** may be in circuit communication between the RF generator **102** and the transmission head **104** and may comprise and pi-network or a tunable pi-network. An exemplary tuning circuit **1000** is shown in FIG. **10** formed with components listed in that figure. Exemplary component values for FIGS. **10**-**16***a* are shown in Table A. Tuning circuit **1000** may be connected between an RF generator **102** and a transmission head **104**. Thus, as shown in FIG. **11** an exemplary system may include an ENI OEM-12B RF generator in circuit communication with exemplary tuning circuit **1000**, which is in circuit communication with exemplary transmission head **900** to generate an RF signal **108** through the reaction chamber **106** by coupling the RF signal **108** to a receiver head **112**. The receiver head **112** may be the same as exemplary receiver head **800**, as shown in the exemplary system of FIG. **11**.

[0044] The exemplary implementation of the exemplary tuning circuit **1000** used in FIGS. **10**-**15** appears to show a voltage gain of about 15-to-1 with respect to the voltage of the RF signal generated by the ENI RF generator. Thus exemplary tuning circuit **1000** may be considered to be a voltage step up transformer. Voltages of the larger plate of the transmission head have been estimated to be in excess of 40,000 volts per inch. Accordingly, some or all of the transmission head and/or the receiving head may be sealed, enclosed in an enclosure, or otherwise encapsulated in an insulating material.

[0045] FIGS. **13**-**15** show different views of an exemplary implementation of portions of the exemplary system of FIG. **12**. As shown in those figures, in implementing the exemplary tuning circuit **1000** used in FIGS. **10**-**12**, the larger inductor L_2 may be positioned with its longitudinal axis substantially coaxial with the central axis of plates of transmission head FP_1, and the central axis of the small inductor L_1 may be substantially perpendicular to the longitudinal axis of the larger inductor L_2. Other components may be used to implement tuning circuit **1000** instead of the exemplary components listed on FIGS. **10**-**12**. For example, the smaller inductor L_1 may be silver-coated or may be made of 12 turns of 5⁄16" copper tubing (or more turns of larger diameter copper tubing) for increased current carrying capacity (smaller inductor L_1 can get relatively hot in exemplary embodiments), and the capacitor C_1 may be made from thirteen (13) 100 pF capacitors instead of eleven (11) for a 1300 pF capacitor C_1. As another example, the plates in the heads may be made of copper (e.g., made from 0.090" copper plate) instead of stainless steel. In the exemplary implementation shown in FIGS. **13**-**15**, a region of the target area slightly closer to the transmission head (about 60/40 distance ratio) heats slightly more than dead center between the two heads. The grounded portion of the components of FIGS. **10**-**15** may be mounted to a copper sheet **1300** or other suitable conducting sheet, and the conducting stand of reception head FP_2 may be mounted on a copper sheet **1500** or other suitable conducting sheet, as shown in FIG. **15**. The grounded plates **1300**, **1500** may be connected by one or more copper straps **1302**.

FIG. 16

[0046] FIG. **16** shows another exemplary system **1600** that is the same as system **1200** (shown in FIGS. **8**A-**8**C, **9**A-**9**C, **12**-**15** and as described above), except the transmission head FP_1' has a single 6" plate, the one 6" circular plate of transmission head FP_1, and the three **6**" and 4" and 3" plates of receiver head FP_2 are made from 0.090" thick copper, capacitor C_1 is 1300 pF instead of 1100 pF, and the smaller inductor L_1 is silver-coated and made of 12 turns of 5⁄16" copper tubing. FIG. **16***a* shows another exemplary system **1600** that is the same as system **1600** except that the receiver head FP_2' has a single 6" circular plate. The transmitting portion and the receiving portion may be enclosed in one or more suitable enclosures, e.g., enclosures **3502**, **3504** in FIG. **22**. Open circuit voltage readings at the transmission head of exemplary physical embodiments have taken. Open circuit voltages of the RF field at 100 W of transmitted power have been measured with a broadband oscilloscope at about 6000 volts (e.g., about 5800 V) peak-to-peak amplitude, which rises to about 22,000 volts at 1000 W of transmitted power (FIG. **16**A in the configuration of FIGS. **13-15**). Additionally, it is believed that in these exemplary systems the voltage and current are not in phase (e.g., out of phase by a certain phase angle). Additionally, perhaps improved RF heating efficiency and/or RF transmission efficiency may be realized by changing the phase relationship between the voltage and current to a predetermined phase angle or real-time determined (or optimal) phase angle. In addition, the Q of exemplary physical embodiments have been estimated using bandwidth (S9 or 3 dB point) in excess of 250 (e.g., 250-290) (FIG. **16**A in the configuration of FIGS. **13-15**). As should be apparent, the RF heating using these exemplary embodiments is significantly different than inductive heating (even substantially different from inductive heating at similar frequencies).

[0047] As shown in FIG. **22**, the circuits may be mounted in two enclosures: a transmission enclosure **3502** and a reception enclosure **3504**, with a reaction chamber **3506** there between. Exemplary transmission enclosure **3502** has grounded metallic walls **3512** on all sides except the side **3513** facing the reception enclosure **3504** (only four such grounded walls **3512***a*-**3512***d* of five such walls **3512** of exemplary transmission enclosure **3502** are shown; the top grounded wall has been removed). Similarly, exemplary reception enclosure **3504** has grounded metallic walls **3514** on all sides except the side **3515** facing the transmission enclosure **3502** (only four such grounded walls **3514***a*-**3514***d* of five such walls **3514** of exemplary reception enclosure **3504** are shown; the top grounded wall has been removed). The grounded walls **3512** of transmission enclosure **3502** are in circuit communication with the grounded walls **3514** of reception enclosure **3504**. Facing walls **3513** and **3515** may be made from TEFLON or another suitable electrical insulator. Transmission enclosure **3502** and/or reception enclosure **3504** may be movably mounted to permit variable spacing between the transmission head and the reception head to accommodate create differently-sized reaction chambers **3506**. Facing walls **3513** and **3515** may have associated openings (not shown) to which various racks and other structures can be connected to support a body part or other target structure between the transmission head and the reception head. Dispersive pads (not shown) may be provided for direct grounding of the target or capacitive grounding of the target structure, which grounding pads may be connected to the grounded walls **3512**, **3514** (such direct or capacitive grounding pads may be help smaller target structures absorb relatively higher levels of RF and heat better). The transmission side components **3522** may be mounted inside exemplary transmission enclosure **3502** and the reception side components **3524** may be mounted inside exemplary reception enclosure **3504**. Exemplary transmission enclosure **3502** and reception enclosure **3504** both may be cooled with temperature-sensing fans that turn on responsive to the heat inside the enclosures **3502**, **3504** reaching a predetermined thermal level. Exemplary transmission enclosure **3502** and reception enclosure **3504** also have a plurality of pass-through connectors, e.g., permitting the RF signal to pass from the RF signal generator into the exemplary transmission enclosure **3502** (perhaps via a power meter) and permitting the received signal to pass outside exemplary reception enclosure **3504** to a power meter and back inside reception enclosure **3504**. In this exemplary embodiment, the enclosures **3502**, **3504** may be moved to vary the spacing between the distal, adjacent ends of the heads from about two inches to a foot or more apart. Various other embodiments may have different ranges of spacing between the distal, adjacent ends of the heads, e.g., from about 2" to about 20" or more apart or from about 2" to about 40" or more apart.

[0048] Each such enclosure may have grounded (e.g., aluminum) walls with a grounded (e.g., copper) base plate, except for the walls proximate the transmission head FP_1' and the reception head FP_2., which may be made from an electrical insulator such as ceramic or TEFLON brand PTFE, e.g., TEFLON brand virgin grade electrical grade PTFE, or another insulator. The walls may be grounded to the copper plate using copper straps and, if a plurality of enclosures are used, the enclosures may have copper strap between then to ground the enclosures together. A long standard fluorescent light bulb can be used to confirm effective grounding (e.g., by turning on the RF signal and repeatedly placing the light bulb proximate the transmission head to illuminate the bulb and then moving the bulb to locations around the enclosure watching for the light bulb to cease illumination, which confirms acceptable grounding). The grounded walls may have a layer of electrical insulator on the inside thereof, such as ceramic or TEFLON brand PTFE, e.g., TEFLON brand virgin grade electrical grade PTFE, or another insulator.

[0049] The exemplary systems of FIGS. **12-16** are believed to generate a very high voltage field in the target area, which very high voltage field can be used to heat many different types of RF absorbing particles as part of RF absorption enhancers in connection with the various methods taught herein. For example, the exemplary systems of FIGS. **12-16** are believed to be capable of heating and combusting salt water solutions in connection with the various methods taught herein.

[0050] FIG. **24** illustrates an exemplary transmission arrangement **2400** that is adapted for at least partial submersion in a liquid. The enclosure includes a sealed circuit housing **2405** in which is enclosed a tuning circuit **2420** and a transmission head **2425**. The tuning circuit receives an RF signal from an RF generator **2410** that may be enclosed in the enclosure as shown or located outside of the enclosure **2405**. An insulated region **2430**, e.g., an air pocket or pocket of another gas, is disposed between the transmission head **2425** and the enclosure **2405**. The enclosure may also include a mounting means, such as a hook or loop **2450**, that is used to mechanically couple the enclosure to a cable or other similar mechanism for lowering the enclosure into a hole or confined treatment area, e.g., with a winch or crane (not shown) or other means for mowering. If the RF generator **2410** is located outside the sealed enclosure **2405**, an insulated electrical conductor (not shown) may be provided to place the circuit **2420** in circuit communication with the RF generator. During construction, air from the portion of the enclosure **2405** surrounding the coupling circuit may be evacuated and the enclosure **2405** filled with an inert gas, such as nitrogen or xenon and then sealed. The coupling circuit may be tunable or not (e.g., pre-tuned), and may be the same as any of the coupling circuits shown or described herein, with virtually any of the transmission heads shown herein. If the coupling circuit portion of the enclosure **2405** is filled with an inert gas, it is believed that much higher powered RF signals may be coupled using the various coupling circuits disclosed herein, e.g., FIGS. **13-15** or FIG. **16***a*. In the alternative, if the coupling circuit portion of the enclosure **2405** is filled with an inert gas, it is believed that significantly smaller coupling circuits may be used vis-á-vis the exemplary coupling circuit of FIGS. **13-15**, because smaller components may be used (by increasing the voltage break down of the coupled components within the enclosure). If the coupling circuit is tunable, such tuning may be accomplished using remotely controllable tunable components, e.g., variable capacitors having stepper motors configured to change the value of the capacitor, or with remote cables to remotely mechanically change the value of the capacitor. Thus, a control unit remove from the enclosure (not shown) may be used to send electrical signals to tune the circuit to reduce or remove reflected power or a user may mechanically remotely tune the circuit to reduce or remove reflected power. Although a grounded reception head (not shown) may be used in this configuration (e.g., also mounted to the enclosure and configured to permit water to flow between the transmission and reception heads or between the insulated region and the reception head) it is believed that it may be possible to tune the circuit without a reception head per se, using the target water as a receiver and a current path (as a sort of grounded reception head).

Methods

[0051] Solutions containing salt water and that optionally contain (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof may be combusted using RF signals by passing a high-voltage RF signal through the solution containing salt water. In a general sense, the methods may be characterized by providing a solution containing salt water and that may optionally contain (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof and passing an RF signal through the solution containing salt water to combust the solution containing salt water (FIG. **23**). Alternatively, in a general sense the methods may be characterized as methods for adding salt to enhance the heating of water or other liquids. Salt water has been combusted using an exemplary system that included a circuit implementation of the circuit of FIG. **16** being used to transmit an RF signal through the salt water to combust the salt water. A solution of OCEANIC brand Natural Sea Salt Mix having a specific gravity of about 1.026 g/cm^3 was used. A 13.56 MHz RF signal from an ENI OEM-12B RF generator having a power of about 800-1000 Watts (e.g., about 900 Watts) was used to combust the salt water.

FIG. 17

[0052] FIG. **17** illustrates a high level exemplary methodology **1700** for producing hydrogen from salt water or from solutions containing salt water.

[0053] The methodology begins at block **1702**. At block **1704** the salt water is provided. The salt water comprises water and at least one salt wherein an effective amount of salt is dissolved in the water. In certain embodiments salt is added to water or other liquids to enhance heating. Optionally, a solution containing salt water may be used that contains salt water and (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof. The salt can be any type of useful salt which is water soluble. Several examples of useful salts are described in greater detail below. An effective amount of salt is the amount of salt necessary to absorb sufficient energy output from the RF signal such that salt water or a solution containing salt water undergoes decomposition to generate hydrogen. OCEANIC brand Natural Sea Salt Mix may be used to approximate the composition of naturally occurring seawater having an effective amount of salt, and that may be used further as either salt water or as the salt water component in a solution containing salt water that is used in the systems and methods discussed and shown herein. Such approximations of naturally occurring seawater may have a specific gravity of about 1.02 g/cm^3 to 1.03 g/cm^3, e.g., between about 1.020-1.024 or about 28-32 PPT, as read off of a hydrometer. As an approximation of naturally occurring seawater, a mixture of water with the above-identified sea salt having a specific gravity of about 1.026 g/cm^3 (as measured with a refractometer) was used in exemplary systems and methods. In the alternative, it is believed that actual seawater may be used in the systems and methods discussed and shown herein.

[0054] It is contemplated that a reservoir of salt water or a solution containing salt water could be made beforehand and stored in a tank such that it would be available upon demand. For example, the storage tank could be connected to the reaction chamber by means of a feed tube. In this manner, a supply of the previously prepared salt water or solution could be pumped from the storage tank into the reaction chamber via the feed tube; wherein the feed tube has one end connected to the storage tank and the other end connected to an inlet present on the reaction chamber. Again, it is believed that ordinary sea water may be used.

[0055] At block **1706** an RF transmitter is provided. The RF transmitter may be any type of RF transmitter generating a suitable RF signal. RF transmitter may be a variable frequency RF transmitter. Optionally, the RF transmitter is also multi-frequency transmitter capable of providing multiple-frequency RF signals. Optionally the RF transmitter is capable of transmitting RF signals with variable amplitudes or pulsed amplitudes. One or more of a variety of different shapes and sizes of transmission and reception heads may be provided.

[0056] The transmission head may be selected at block **1708**. The selection of the transmission head may be based in part on the type of RF transmitter provided. Other factors, such as, for example, the depth, size and shape of the general target area, or specific target area to be treated, and the number of frequencies transmitted may also be used in determining the selection of the transmission head.

[0057] The RF receiver is provided at block **1710**. The RF receiver may be tuned to the frequency(s) of the RF transmitter. At block **1712**, the desired receiver head may be selected. Similarly to the selection of the transmission head, the receiver head may be selected to fit the desired characteristics of the particular application. For example, a receiver head that is larger than the transmission head can be selected to concentrate the RF signal on a specific area in the reaction chamber (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature). For example, a single 6" circular copper plate may be used on the Tx side and a single square 9.5" copper plate may be used on the Rx side. In this manner, selection of various sizes and shapes of the receiver heads allow for optimal concentration of the RF signal in the salt water mixture.

[0058] At block **1714** the transmission head is arranged. Arrangement of the transmission head is accomplished by, for example, placing the transmission head proximate to and on one side of the reaction chamber. At block **1716** the receiver head is arranged. Arrangement of the receiver head is similarly accomplished by, for example, placing the receiver head proximate to and on the other side of the reaction chamber so that an RF signal transmitted via the transmission head to the receiver head will pass through the reaction chamber and be absorbed by the salt water or the salt water component of the solution containing salt water. The transmission head and reception heads are insulated from direct contact with the reaction chamber. The heads may be insulated from the reaction chamber by means of an air gap. Optionally, the heads may be insulated from the target area by means of another insulating material.

[0059] The RF frequency(s) may be selected at block **1718**. In addition to selecting the desired RF frequency(s) at block **1718**, the transmission time or duration may also be selected. The duration time is set to, for example, a specified length of time, or set to raise the temperature of at least a portion of the salt water or the solution containing salt water to a desired temperature/temperature range, or set to a desired change in temperature. In addition, optionally, other modifications of the RF signal may be selected at this time, such as, for example, amplitude, pulsed amplitude, an on/off pulse rate of the RF signal, a variable RF signal where the frequency of the RF signal varies over a set time period or in relation to set temperatures, ranges or changes in temperatures.

[0060] At block **1720** the RF signal is transmitted from the transmission head to the receiver head. The RF signal passes through the reaction chamber and is absorbed by the salt water or the salt water component of the solution containing salt water that is contained within the reaction chamber. Absorption of the RF energy results in decomposition of the salt water or the salt water component of the solution containing salt water to generate hydrogen.

[0061] At block **1722** the hydrogen produced by decomposition of a salt water or solution containing salt water is collected. Hydrogen may be collected by any means. An example of a means for collecting hydrogen would be to utilize a vacuum or pump apparatus to remove the hydrogen gas as it is produced and to then retain the hydrogen in a location physically separated from the reaction chamber. For example, such a vacuum or pump apparatus could have one end attached to an outlet present on the reaction chamber and the other end attached to a gas storage container. It is contemplated that the gas storage container may be fitted with valves, as for example a one way valve, such that gas could enter or be pumped into the tank but then the gas could not leave the tank.

[0062] The methodology may end at block **1724** and may be ended after a predetermined time interval and/in response to a determination that a desired amount of hydrogen production has been achieved. The method may be performed once or repeatedly, or continuously, or periodically, or intermittently.

FIGS. **18**(*a*) and **18**(*b*)

[0063] FIG. **18**(*a*) illustrates a high level exemplary methodology **1800** for producing hydrogen from salt water and subsequently for the combustion of the hydrogen produced. FIG. **18**(*b*) illustrates a high level exemplary methodology **1800** for (i) sufficiently heating a solution containing salt water that may optionally contain a secondary fuel in order to volatilize and combust the secondary fuel; or (ii) decomposing the salt water component of the solution containing salt water to generate hydrogen and to subsequently combust the hydrogen produced; or (iii) both.

[0064] The methodology for both FIGS. **18**(*a*) and **18**(*b*) begins at block **1802**. At block **1804** either salt water or a solution containing salt water is provided. In FIG. **18**(*a*) the salt water comprises water and at least one salt, wherein an effective amount of salt is dissolved in the water. In certain embodiments salt is added to water or other liquids to enhance heating. In FIG. **18**(*b*) the salt water solution comprises the salt water of FIG. **18**(*a*) and optionally: (i) at least one additive, or (ii) at least one secondary fuel source, or (iii) mixtures thereof. The salt used in FIGS. **18**(*a*)-(*b*) can be any type of useful salt which is water soluble. Several examples of useful salts are described in greater detail below. An effective amount of salt is the amount of salt necessary to allow surrounding water to absorb sufficient energy output from the RF signal such that it undergoes decomposition to generate hydrogen, or the amount of salt necessary to allow surrounding water to absorb sufficient energy output from the RF signal such that it undergoes sufficient heating to volatilize and combust any secondary fuel source optionally present. OCEANIC brand Natural Sea Salt Mix may be used to approximate the composition of naturally occurring seawater having an effective amount of salt and that may be used further as the salt water component of the salt water containing solution in the systems and methods discussed and shown herein. Such approximations of naturally occurring seawater may have a specific gravity of about 1.02 g/cm^3 to 1.03 g/cm^3, e.g., between about 1.020-1.024 or about 28-32 PPT, as read off of a hydrometer. As an approximation of naturally occurring seawater, a mixture of water with the above-identified sea salt having a specific gravity of about 1.026 g/cm^3 (as measured with a refractometer) was used in exemplary systems and methods. In the alternative, it is believed that actual seawater may be used in the systems and methods discussed and shown herein.

[0065] It is contemplated that a reservoir of salt water or a solution containing salt water could be made beforehand and stored in a tank such that it would be available upon demand. For example, the storage tank could be connected to the reaction chamber by means of a feed tube. In this manner, a supply of the salt water or the salt water containing solution previously prepared could be pumped from the storage tank into the reaction chamber via the feed tube; wherein the feed tube has one end connected to the storage tank and the other end connected to an inlet present on the reaction chamber.

[0066] At block **1806** an RF transmitter is provided. The RF transmitter may be any type of RF transmitter generating a suitable RF signal. RF transmitter may be a variable frequency RF transmitter. Optionally, the RF transmitter may also be a multi-frequency transmitter capable of providing multiple-frequency RF signals. Still yet, optionally the RF transmitter may be capable of transmitting RF signals with variable amplitudes or pulsed amplitudes. A variety of different shapes and sizes of transmission and reception heads may be provided.

[0067] The transmission head may be selected at block **1808**. The selection of the transmission head may be based in part on the type of RF transmitter provided. Other factors, such as, for example, the depth, size and shape of the general target area, or specific target area to be treated, and the number of frequencies transmitted may also be used in determining the selection of the transmission head.

[0068] The RF receiver is provided at block **1810**. The RF receiver may be tuned to the frequency(s) of the RF transmitter. At block **1812**, the desired receiver head may be selected. Similarly to the selection of the transmission head, the receiver head may be selected to fit the desired characteristics of the particular application. For example, a receiver head that is larger than the transmission head can be selected to concentrate the RF signal on a specific area in the reaction chamber (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature). Various sizes and shapes of the receiver heads allow for optimal concentration of the RF signal in the salt water and solutions containing salt water.

[0069] At block **1814** the transmission head is arranged. Arrangement of the transmission head is accomplished by, for example, placing the transmission head proximate to and on one side of the reaction chamber. At block **1816** the receiver head is arranged. Arrangement of the receiver head is similarly accomplished by, for example, placing the receiver head proximate to and on the other side of the reaction chamber so that an RF signal transmitted via the transmission head to the receiver head will pass through the reaction chamber and be absorbed by the salt water or the salt water component of a solution containing salt water. The transmission head and reception heads are insulated from direct contact with the reaction chamber. The heads may be insulated from the reaction chamber by means of an air gap. Optionally, the heads may be insulated from the target area by means of another insulating material.

[0070] The RF frequency(s) may be selected at block **1818**. In addition to selecting the desired RF frequency(s) at block **1818**, the transmission time or duration may also be selected. The duration time is set to, for example, a specified length of time, or set to raise the temperature of at least a portion of the salt water or the solution containing salt water to a desired temperature/temperature range, or set to a desired change in temperature. In addition, optionally, other modifications of the RF signal may be selected at this time, such as, for example, amplitude, pulsed amplitude, an on/off pulse rate of the RF signal, a variable RF signal where the frequency of the RF signal varies over a set time period or in relation to set temperatures, ranges or changes in temperatures.

[0071] At block **1820** the RF signal is transmitted from the transmission head to the receiver head. The RF signal passes through the reaction chamber and is absorbed by the salt water or the salt water component of the solution containing salt water that is present within the reaction chamber. In FIG. **18**(*a*), absorption of the RF energy initially results in decomposition of the salt water to produce hydrogen, while still further absorption of the RF energy eventually leads to the combustion of the hydrogen produced by the decomposition of the salt water. In FIG. **18**(*b*), absorption of the RF energy initially results in (i) sufficiently heating the solution containing salt water in order to volatilize and to combust any secondary fuel that may be optionally present; or (ii) decomposition of the salt water component of the solution containing salt water to generate hydrogen; or (iii) both.

[0072] The methodology may end at block **1822** and may be ended after a predetermined time interval and/in response to a determination that a desired amount of hydrogen production and hydrogen combustion, or alternatively a desired amount of volatilization and combustion of the secondary fuel that may be optionally present is achieved. The method may be performed once or repeatedly, or continuously, or periodically, or intermittently.

FIGS. **19**(*a*) and **19**(*b*)

[0073] FIG. **19**(*a*) illustrates a high level exemplary methodology **1900** for producing hydrogen from salt water, for the combustion of the hydrogen produced, and for the subsequent conversion of this chemical energy into mechanical energy that moves a piston. FIG. **19**(*b*) illustrates a high level exemplary methodology **1900** for (i) sufficiently heating a solution containing salt water that may optionally contain a secondary fuel in order to volatilize and combust the secondary fuel; or (ii) decomposing the salt water component of the solution containing salt water to generate hydrogen and to subsequently combust the volatilized secondary fuel source or the hydrogen produced; or (iii) both; and for the subsequent conversion of the chemical energy that combustion releases into mechanical energy that moves a piston.

[0074] The methodology for both FIGS. **19**(*a*) and **19**(*b*) begins at block **1902**. At block **1904** either salt water or a solution containing salt water is provided. In FIG. **19**(*a*) the salt water comprises water and at least one salt wherein an effective amount of salt is dissolved in the water. In certain embodiments salt is added to water or other liquids to enhance heating. In FIG. **19**(*b*) the solution containing salt water comprises the salt water from FIG. **19**(*a*) and optionally (i) at least one additive, or (ii) at least one secondary fuel, or (iii) mixtures thereof. The salt can be any type of useful salt which is water soluble. Several examples of useful salts are described in greater detail below. An effective amount of salt is the amount of salt necessary to allow surrounding water to absorb sufficient energy output from the RF signal such that it undergoes decomposition to generate hydrogen, or the amount of salt necessary to allow surrounding water to absorb sufficient energy output from the RF signal such that it undergoes sufficient heating to volatilize and combust any secondary fuel source optionally present. OCEANIC brand Natural Sea Salt Mix may be used to approximate the composition of naturally occurring seawater having an effective amount of salt and that may be used further as the salt water component of the solutions containing salt water that are used in the systems and methods discussed and shown herein. Such approximations of naturally occurring seawater may have a specific gravity of about 1.02 g/cm^3 to 1.03 g/cm^3, e.g., between about 1.020-1.024 or about 28-32 PPT, as read off of a hydrometer. As an approximation of naturally occurring seawater, a mixture of water with the above-identified sea salt having a specific gravity of about 1.026 g/cm^3 (as measured with a refractometer) was used in exemplary systems and methods. In the alternative, it is believed that actual seawater may be used in the systems and methods discussed and shown herein.

[0075] It is contemplated that a reservoir of the salt water or a solution containing salt water could be made beforehand and stored in a tank such that it would be available upon demand. For example, the storage tank could be connected to the reaction chamber by means of a feed tube. In this manner, a supply of the salt water or the solution containing salt water previously prepared could be pumped from the storage tank into the reaction chamber via the feed tube; wherein the feed tube has one end connected to the storage tank and the other end connected to an inlet present on the reaction chamber. Alternatively, it is contemplated that a spray nozzle could be attached onto the end of the feed tube leading into the inlet present on the reaction chamber. In this arrangement it is believed that the salt water or the solution containing salt water could be introduced into the reaction chamber in the form of a mist or spray.

[0076] At block **1906** an RF transmitter is provided. The RF transmitter may be any type of RF transmitter generating a suitable RF signal. RF transmitter may be a variable frequency RF transmitter. Optionally, the RF transmitter may also be a multi-frequency transmitter capable of providing multiple-frequency RF signals. Still yet, optionally the RF transmitter may be capable of transmitting RF signals with variable amplitudes or pulsed amplitudes. A variety of different shapes and sizes of transmission and reception heads may be provided.

[0077] The transmission head may be selected at block **1908**. The selection of the transmission head may be based in part on the type of RF transmitter provided. Other factors, such as, for example, the depth, size and shape of the general target area, or specific target area to be treated, and the number of frequencies transmitted may also be used in determining the selection of the transmission head.

[0078] The RF receiver is provided at block **1910**. The RF receiver may be tuned to the frequency(s) of the RF transmitter. At block **1812**, the desired receiver head may be selected. Similarly to the selection of the transmission head, the receiver head is may be selected to fit the desired characteristics of the particular application. For example, a receiver head that is larger than the transmission head can be selected to concentrate the RF signal on a specific area in the reaction chamber (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature). Various sizes and shapes of the receiver heads allow for optimal concentration of the RF signal in the salt water and solution containing salt water.

[0079] At block **1914** the transmission head is arranged. Arrangement of the transmission head is accomplished by, for example, placing the transmission head proximate to and on one side of the reaction chamber. At block **1916** the receiver head is arranged. Arrangement of the receiver head is similarly accomplished by, for example, placing the receiver head proximate to and on the other side of the reaction chamber so that an RF signal transmitted via the transmission head to the receiver head will pass through the reaction chamber and be absorbed by the salt water or the salt water component of a solution containing salt water. The transmission head and receiving heads are insulated from direct contact with the reaction chamber. The heads may be insulated from the reaction chamber by means of an air gap. Optionally, the heads are insulated from the target area by means of another insulating material.

[0080] The RF frequency(s) may be selected at block **1918**. In addition to selecting the desired RF frequency(s) at block **1918**, the transmission time or duration may also be selected. The duration time is set to, for example, a specified length of time, or set to raise the temperature of at least a portion of the salt water or salt water solution to a desired temperature/temperature range, or set to a desired change in temperature. In addition, optionally, other modifications of the RF signal may be selected at this time, such as, for example, amplitude, pulsed amplitude, an on/off pulse rate of the RF signal, a variable RF signal where the frequency of the RF signal varies over a set time period or in relation to set temperatures, ranges or changes in temperatures.

[0081] At block **1920** the RF signal is transmitted from the transmission head to the receiver head. The RF signal passes through the reaction chamber and is absorbed by the salt water or the salt water component of the salt water containing solution present within the reaction chamber. In FIG. **19**(*a*), absorption of the RF energy initially results in decomposition of the salt water to produce hydrogen, while still further absorption of the RF energy eventually leads to the combustion of the hydrogen produced by the decomposition of the salt water. In FIG. **19**(*b*), absorption of the RF energy initially results in (i) sufficiently heating the solution containing salt water in order to volatilize and to combust any secondary fuel that may be optionally present; or (ii) decomposition of the salt water component of the aqueous solution to generate hydrogen; or (iii) both.

[0082] Alternatively, it is contemplated that an ignition source, for example a spark plug, could be attached to the reaction chamber. This ignition source would also be in circuit communication with a current source, such as for example a battery. The arrangement contemplated here would provide for a current going to the ignition source to be switched on and off when desired. This would result in generation of an ignition event, as for example with a spark plug a spark would be produced, on demand. It is believed that this ignition event would cause the combustion of the hydrogen that had been produced by the decomposition of the salt water, or would cause the combustion of either the hydrogen or any volatilized secondary fuel or both that is produced by RF treatment of a solution containing salt water in the reaction chamber.

[0083] At block **1922**, the energy generated from the combustion of hydrogen, which is produced from the decomposition of the salt water (or more generally, the energy generated from either (i) combustion of the hydrogen produced from decomposition of the salt water, or (ii) the volatilization and combustion of any secondary fuel that may be optionally present in a solution containing salt water, or (iii) both), is transmitted to a piston in order to perform mechanical work. In any event, the combustion of either the hydrogen or any secondary fuel or both generates hot exhaust gases including steam. These hot exhaust gases expand and in doing so create an increase in pressure. It is contemplated that the head of a piston could be attached to the outlet present on the reaction chamber and the other end of piston attached to a lever arm. As expanding exhaust gases push against the piston head, the lever arm is moved transforming the chemical energy of expanding exhaust gases into mechanical energy and into the performance of mechanical work.

[0084] It is further contemplated that this piston arrangement could be utilized together with the spray nozzle and ignition source described above, to allow one to convert chemical energy into mechanical energy and subsequently into the performance of mechanical work, on demand. For example, this method could be used in such an arrangement in order to power an internal combustion engine. It is further contemplated that one example of how this method together with the appropriate system could be utilized, would be in providing an engine that would be fueled by salt water or various solutions containing salt water, or even directly by seawater taken from the ocean without further purification, rather than requiring gasoline or other water incompatible hydrocarbon fuels to operate. Specifically, it is contemplated that this engine could be provided in an appropriate size and in a manner such that it could be used to power an automobile or other form of motorized vehicle.

[0085] The methodology may end at block **1924** and may be ended after a predetermined time interval and/in response to a determination that a desired amount of hydrogen production and hydrogen combustion, or alternatively that a desired amount of volatilization and combustion of any secondary fuel source that is optionally present has been achieved. The method may be performed once or repeatedly, or continuously, or periodically, or intermittently.

FIG. 20

[0086] FIG. **20** illustrates a high level exemplary methodology **2000** for desalinating seawater.

[0087] The methodology begins at block **2002**. At block **2004** seawater is provided. Any manner of seawater from any ocean or of any concentration or salinity would suffice. Furthermore, it is contemplated that the seawater could be taken from the source in its natural occurring form and used directly without the need for any further purification or processing. Examples of several sources for seawater are described below. It is also contemplated that an amount of seawater could be stored in a reservoir or storage tank such that it would be available to fill the reaction chamber upon demand. For example, the storage tank could be connected to the reaction chamber by means of a feed tube. In this manner, a supply of seawater could be pumped from the storage tank into the reaction chamber via the feed tube; wherein the feed tube has one end connected to the storage tank and the other end connected to an inlet present on the reaction chamber.

[0088] At block **2006** an RF transmitter is provided. The RF transmitter may be any type of RF transmitter generating a suitable RF signal. RF transmitter may be a variable frequency RF transmitter. Optionally, the RF transmitter may also be a multi-frequency transmitter capable of providing multiple-frequency RF signals. Still yet, optionally the RF transmitter may be capable of transmitting RF signals with variable amplitudes or pulsed amplitudes. A variety of different shapes and sizes of transmission and reception heads are provided.

[0089] The transmission head may be selected at block **2008**. The selection of the transmission head may be based in part on the type of RF transmitter provided. Other factors, such as, for example, the depth, size and shape of the general target area, or specific target area to be treated, and the number of frequencies transmitted may also be used in determining the selection of the transmission head.

[0090] The RF receiver is provided at block **2010**. The RF receiver may be tuned to the frequency(s) of the RF transmitter. At block **2012**, the desired receiver head may be selected. Similarly to the selection of the transmission head, the receiver head may be selected to fit the desired characteristics of the particular application. For example, a receiver head that is larger than the transmission head can be selected to concentrate the RF signal on a specific area in the reaction chamber (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature). Various sizes and shapes of the receiver heads allow for optimal concentration of the RF signal in the seawater.

[0091] At block **2014** the transmission head is arranged. Arrangement of the transmission head is accomplished by, for example, placing the transmission head proximate to and on one side of the reaction chamber. At block **2016** the receiver head is arranged. Arrangement of the receiver head is similarly accomplished by, for example, placing the receiver head proximate to and on the other side of the reaction chamber so that an RF signal transmitted via the transmission head to the receiver head will pass through the reaction chamber and be absorbed by the seawater. The transmission head and reception heads are insulated from direct contact with the reaction chamber. The heads may be insulated from the reaction chamber by means of an air gap. Optionally, the heads may be insulated from the target area by means of another insulating material.

[0092] The RF frequency(s) may be selected at block **2018**. In addition to selecting the desired RF frequency(s) at block **2018**, the transmission time or duration may also be selected. The duration time is set to, for example, a specified length of time, or set to raise the temperature of at least a portion of the seawater to boiling. In addition, optionally, other modifications of the RF signal are selected at this time, such as, for example, amplitude, pulsed amplitude, an on/off pulse rate of the RF signal, a variable RF signal where the frequency of the RF signal varies over a set time period or in relation to set temperatures, ranges or changes in temperatures or desired phase transitions.

[0093] At block **2020** the RF signal is transmitted from the transmission head to the receiver head. The RF signal passes through the reaction chamber and is absorbed by the seawater contained within the reaction chamber. Absorption of the RF energy results in heating of the seawater causing the seawater to undergo a phase change and produce steam. The steam produced would be free of any salt, minerals, or any other nonvolatile impurities initially present in the seawater.

[0094] At block **2022** the steam produced by heating the seawater to boiling is collected. At block **2024** the collected steam is condensed to form purified water. The steam may be collected by any means. An example of a means for collecting and condensing steam would be to utilize a the natural tendency of hot gases, such as steam, to rise. For example, it is contemplated that an exhaust pipe having one end attached to the outlet present in the reaction chamber and positioned to be directly above the reaction chamber could conduct the steam, as it is produced, away from the reaction chamber. It is further contemplated that the other end of the exhaust pipe could be attached to a remotely positioned tank and that this tank would functioned as a condenser such that, upon entering the tank, the steam would cool and convert phases from steam into water. As a result, it is believed that purified water would be condensed and collect in such a condenser tank. It is contemplated that, optionally, the condenser tank could be externally cooled in order to facilitate the rate of condensation of the steam.

[0095] The methodology may end at block **2026** and may be ended after a predetermined time interval and/in response to a determination that a desired amount of steam production and desalination has been achieved. The method may be performed once or repeatedly, or continuously, or periodically, or intermittently.

FIG. 21

[0096] FIG. **21** illustrates a high level exemplary methodology **2100** of carrying out the electrolysis of water.

[0097] The methodology begins at block **2102**. At block **2104** a salt water mixture is provided. The salt water mixture comprises water and at least one salt wherein an effective amount of salt is dissolved in the water. The salt should be water soluble and, in order to effectively form both hydrogen and oxygen gases, the salt should be selected such that the corresponding cation of the salt has a lower standard electrode potential than H^+ and the corresponding anion of the salt has a higher standard electrode potential than OH^-. A more detailed description of various salts and their effective amounts which are useful in this regard is given below.

[0098] At block **2106** an RF transmitter is provided. The RF transmitter may be any type of RF transmitter generating a suitable RF signal. RF transmitter may be a variable frequency RF transmitter. Optionally, the RF transmitter may also be a multi-frequency transmitter capable of providing multiple-frequency RF signals. Still yet, optionally the RF transmitter may be capable of transmitting RF signals with variable amplitudes or pulsed amplitudes. A variety of different shapes and sizes of transmission and reception heads may be provided.

[0099] The transmission head may be selected at block **2108**. The selection of the transmission head may be based in part on the type of RF transmitter provided. Other factors, such as, for example, the depth, size and shape of the general target area, or specific target area to be treated, and the number of frequencies transmitted may also be used in determining the selection of the transmission head.

[0100] The RF receiver is provided at block **2110**. The RF receiver may be tuned to the frequency(s) of the RF transmitter. At block **2112**, the desired receiver head may be selected. Similarly to the selection of the transmission head, the receiver head may be selected to fit the desired characteristics of the particular application. For example, a receiver head that is larger than the transmission head can be selected to concentrate the RF signal on a specific area in the reaction chamber (although it was earlier believed that a smaller head would concentrate the RF to enhance RF heating, a larger reception head was found to generate a higher temperature). Various sizes and shapes of the receiver heads allow for optimal concentration of the RF signal in the salt water mixture.

[0101] At block **2114** the transmission head is arranged. Arrangement of the transmission head is accomplished by, for example, placing the transmission head proximate to and on one side of the reaction chamber. At block **2116** the receiver head is arranged. Arrangement of the receiver head is similarly accomplished by, for example, placing the receiver head proximate to and on the other side of the reaction chamber so that an RF signal transmitted via the transmission head to the receiver head will pass through the reaction chamber and be absorbed by the salt water mixture. The transmission head and reception heads are insulated from direct contact with the reaction chamber. The heads may be insulated from the reaction chamber by means of an air gap. Optionally, the heads are insulated from the target area by means of another insulating material.

[0102] The RF frequency(s) may be selected at block **2118**. In addition to selecting the desired RF frequency(s) at block **2118**, the transmission time or duration may also be selected. The duration time is set to, for example, a specified length of time, or set to raise the temperature of at least a portion of the salt water mixture to a desired temperature/temperature range, or set to a desired change in temperature. In addition, optionally, other modifications of the RF signal are selected at this time, such as, for example, amplitude, pulsed amplitude, an on/off pulse rate of the RF signal, a variable RF signal where the frequency of the RF signal varies over a set time period or in relation to set temperatures, ranges or changes in temperatures.

[0103] At block **2120** the RF signal is transmitted from the transmission head to the receiver head. The RF signal passes through the reaction chamber and is absorbed by the salt water mixture contained within the reaction chamber. Absorption of the RF energy results in decomposition of the salt water mixture to produce hydrogen and oxygen.

[0104] At block **2122** both the hydrogen and oxygen produced by decomposition of the salt water mixture is collected. Means for collecting and separating the hydrogen and oxygen produced by the electrolysis of the salt water mixture will be known to those skilled in the art. Such techniques may include using two evacuated, gas collection bells that are nested within one another; where the opening to the innermost gas collection bell is covered with a semi-permeable membrane. The semi-permeable membrane may be made from a material that has a greater permeability to hydrogen gas than it does to oxygen gas. In this regard, as the mixture of hydrogen and oxygen gases are directed using a series of tubes and valves towards the two gas collection bells nested within one another, only hydrogen gas would be able to effectively pass through the membrane covering the innermost gas collection bell. As such, the hydrogen gas would become concentrated in the innermost gas collection bell, while the oxygen gas would become concentrated in the outermost gas collection bell. In this manner, it is believed that the hydrogen gas could be isolated and collected separately from the oxygen gas.

[0105] The methodology ends at block **2124** and may be ended after a predetermined time interval and/in response to a determination that a desired amount of hydrogen production has been achieved.

FIG. **25**

[0106] FIG. **25** illustrates a high level exemplary methodology **2500** of carrying out the combustion of a liquid. The methodology begins at block **2510**. At block **2510** an RF system is provided that is capable of generating an RF signal. The RF system may include an RF generator, transmitter and transmission head and be of the type described above such that it is capable of generating an ignitable gas from sea water in an open container proximate to the transmission head. At block **2520** a liquid is provided that includes an effective amount of at least one ion dissolved in the liquid for generation of an ignitable gas by the RF signal. At block **2530** the RF signal is transmitted such that it interacts with at least some of the liquid. At block **2540** the ignitable gas generated from the liquid by the RF signal is ignited. At block **2550** the methodology ends and may be ended after a predetermined time interval and/in response to a determination that a portion of the liquid has been combusted.

FIG. **26**

[0107] FIG. **26** illustrates a high level exemplary methodology **2600** of carrying out the combustion of a liquid. The methodology begins at block **2610**. At block **2610** an RF system is provided that is capable of generating an RF signal. The RF system may include an RF generator, transmitter, and transmission head and be of the type described above such that it is capable of generating an ignitable gas from sea water in an open container proximate to the transmission head. At block **2620** a liquid is provided that includes an effective amount of at least one ion dissolved in the liquid for generation of an ignitable gas by the RF signal. At block **2630** the RF signal is transmitted and at block **2640** a portion of the liquid is combusted.

[0108] Additional methods are contemplated using the systems described herein where a frequency for operation of the RF signal may be selected such that the frequency is the same as, or overlaps (either partially or completely)—or has harmonics that are the same as or overlaps—specific RF frequencies that are capable of stimulating or exciting any of the various energy levels of various ions, e.g., any of the various metal species that comprise the salts that are dissolved in the salt water solutions. One having ordinary skill in the art will understand how to determine and to measure RF frequencies that stimulate or excite various energy levels for various metal species. In this regard and based on empirical testing, we believe that 13.56 MHz stimulates and/or excites Na ions better than any other ions herein so tested. As such, it is believed that useful embodiments of the methods described herein may therefore also include (i) selecting an RF signal having a preferred frequency, (ii) selecting a metal salt comprising a metal species capable of being stimulated or excited by the preferred frequency selected (or a harmonic thereof), (iii) transmitting the RF signal having the preferred frequency through or to an aqueous solution of the metal salt for a sufficient time in order to stimulate or excite the metal species present in the aqueous solution to generate heat. Alternatively, methods may also include (i) selecting a salt comprising a preferred metal species, (ii) selecting an RF signal having a frequency (or a harmonic thereof) capable of stimulating or exciting the preferred metal species, (iii) transmitting the RF signal having the frequency to or through an aqueous solution of the metal salt comprising the preferred metal species for a sufficient time to generate heat.

[0109] Additional methods are contemplated using the systems described herein where the RF signal may be used to process clays and soils to heat and sterilize the clays and soils, to directly generate hydrogen from the clays and soils, and for remediation of the clays or soils by removing or extracting organic contaminants and wastes. It is contemplated, as above, that a frequency for operation of the RF signal may be selected such that the frequency (or a harmonic thereof) is the same as or overlaps with (either partially or completely) specific RF frequencies capable of stimulating or exciting any of the various energy levels of any of the various metal species comprising metal salts or metal compounds that are dissolved or distributed within the soils. Since soils often contain moisture or the metal species present in the soils and clays have water molecules coordinated to them, it is therefore believed that the systems and methods described herein could be used to heat and process such metal-containing soils. As such, we believe the RF signal could be used (in any of the various manners herein described for treatment of salt water solutions) to produced heat and/or steam and/or hydrogen and oxygen free radicals in-situ within various soils, and in particular in clays and clay containing soils. The heat and/or the steam and/or the hydrogen and oxygen free radical produced from the water molecules present in the soil would treat the surrounding soil, in particular the heat and/or the free radicals generated would perhaps sterilize the soil, killing any animal, vegetable or microbial life that may also be present. It is further contemplated that steam produced in-situ in this manner may also be used to volatize and extract any hydrocarbon pollutants that may also be present in the soils and clays. As such, it is contemplated that soils of contaminated commercial residential and industrial sites, hazardous waste dump sites, gas stations, etc. could be remediated using the systems and methods described herein. One skilled in the art will understand how the RF systems and methods described herein could be coupled with known extraction and remediation processes and methods for in-situ treatment of contaminated soils. Exemplary hydrocarbon contaminants that could be extracted or removed would include but are not limited to organic solvents, oil and oil byproducts, insecticides, and polychlorinated biphenyls. Similarly, it is contemplated that clathrates, zeolites, and other materials containing or having various metal species adsorbed to their surfaces or in there structures and containing either moisture or water molecules coordinated to the metal species present may be processed and heated in similar manners as has been described herein for soils and clays.

[0110] In accordance with the systems and methods of the present invention previously described, further embodiments are contemplated of an RF system for selective disinfection of surfaces and materials is provided. The system includes an RF transmitter having an RF generator and a transmission head, and an RF receiver having a resonant circuit and a reception head. When the transmission and reception heads are arranged proximate to and on either side of a surface or material and an RF signal is transmitted from the transmission head, through the surface or material, to the reception head, at least a portion of the surface or material is disinfected without direct contact of the heads to the surface or material. It is contemplated, as above, that a frequency for operation of the RF signal may be selected such that the frequency (or harmonic thereof) is the same as or overlaps with (either partially or completely) specific RF frequencies that are capable of stimulating or exciting any of the various energy levels of any of the various metal species or metal salts or metal compounds that may, for example, be present within various targeted microbes, bacteria, or viruses. Since environments where microbes, bacteria, and viruses are found also often contain moisture, we therefore believe that the systems and methods described herein could be used to disinfect surfaces and materials through selectively heating and destroying various targeted microbes, bacteria, and viruses that are present on the surfaces or materials to be disinfected. The RF signal would be applied for a sufficient time to locally heat and destroy any targeted microbes, bacteria, and viruses that contain metals (metals that are either coordinated by water molecules or in an environment containing moisture) that are stimulated or excited by the RF signal having the particular frequency so selected.

[0111] In accordance with the systems and methods of the present invention previously described, further embodiments are contemplated of an RF system for affecting a change in the germination and growth of plant life is provided. The system includes an RF transmitter having an RF generator and a transmission head, and an RF receiver having a resonant circuit and a reception head. When the transmission and reception heads are arranged proximate to and on either side of a seed or a plant and an RF signal is transmitted from the transmission head, through the seed or plant, to the reception head, at least a portion of the seed or plant is processed without direct contact of the heads to the seed or plant. For example, a seed may be placed in a brackish environment or a plant may be watered with brine solution and natural biological processes such as osmotic pumping mechanisms may be taken advantage of in order to create a seed or plant having an internal environment with an increased salt concentration. We believe that any of the systems or methods described herein may be used to then expose the so prepared seed or plant to an RF signal, wherein the RF signal would affect a change in the rate of germination of the seed or affect a change in the rate of growth of the plant. We believed that that a frequency for operation of the RF signal may be selected such that the frequency (or harmonic thereof) is the same as or overlaps with (either partially or completely) specific RF frequencies that are capable of either increasing or decreasing the rates of seed germination and plant growth in order to affect such a change in the germination and growth of plant life.

[0112] In accordance with the systems and methods of the present invention previously described, further embodiments contemplating RF systems and methods for processing a fluid are provided. Processing a fluid includes but is not limited to heating and/or combusting the fluid. Fluids can be processed whether or not they contain any of the useful salts or ions (either cations or anions) herein described. An exemplary fluid in this regard includes but is not limited to water that is extracted from oil wells and that is contaminated with oil residues and/or other hydrocarbon contaminants. Methods for processing (including heating and/or combusting) a fluid involve using any of the systems previously described and (i) providing a fluid to be processed (including heating and/or combusting the fluid), (ii) adding an effective amount of salt to the fluid (e.g., by adding solid salt or by adding a salt solution), and (iii) passing RF through the fluid containing an effective amount of salt to process the fluid. In general, useful systems may include an RF transmitter having an RF generator and a transmission head, and an RF receiver having a resonant circuit and a reception head. When the transmission and reception heads are arranged proximate to and on either side of the fluid having an effective amount of salt added to it an RF signal is transmitted from the transmission head, through the fluid containing the salt, to the reception head, and at least a portion of the fluid is processed. Processing in this regard may include heating the fluid and/or combusting the fluid and in such situations salt is added to enhance heating of the fluid.

Salt Water, Salt Water Solutions, and Salt Water Mixtures

[0113] Ordinary and naturally occurring seawater may be used. Generally, a salt which is useful as the salt water or in the solution containing salt water or in the salt water mixtures employed in these systems and methods disclosed herein include any salt which has solubility in water. For example, NaCl is a useful salt because NaCl is very soluble in water. Other useful salts may include salts that have as their cation any element in cationic form, which may selected from the group consisting of Li^+, Na^+, K^+, Rb+, Cs^+, Be^{2+}, Mg^{2+}, Ca^{2+}, Ba^{2+}, Sr^{2+}, Mn^{2+}, Fe^{2+}, Fe^{3+}, Ni^{2+}, Cu^{2+}, Zn^{2+}, Ag^+, Au^+, B^{3+}, Al^{3+}, Ga^{3+}, In^{3+} and that have as the anion any element in anionic form that is selected from the group consisting of Cl^-, Br^-, I^-, borate, citrate, nitrate, phosphate, sulfate, carbonate, and hydroxide. The salt used in the systems and methods disclosed herein can be used as either a pure salt, the salt made from one type of cation and one type of anion that are those cations and anions listed above; or it can be a salt mixture, made from more than one type salt, made from one or more types of cations and/or one or more types of anions that are those cations and anions listed above. Again, ordinary and naturally occurring seawater may be used.

[0114] Another useful salt water (or salt water component of either solutions containing salt water or salt water mixtures) for use in the systems and methods disclosed herein is seawater. This includes all types of seawater, including water taken from any of the oceans or other naturally salty bodies of water found on the earth. Using seawater as disclosed herein includes using seawater in its natural occurring form, that is, seawater which is taken from the ocean and used directly without any further processing or purification.

[0115] Another useful salt water or salt water solution for use in the systems and methods disclosed herein is brine water. Brine water may be water extracted from the ground (ground water) and includes water that is taken from water wells and oil wells. Using brine water as disclosed herein includes using brine water that has been further processed or treated (for example, by addition of salt, e.g., adding solid salt or a salt solution) or that is in its naturally occurring form and used directly without any further processing or purification.

[0116] OCEANIC brand Natural Sea Salt Mix may be used to approximate naturally occurring seawater having an effective amount of salt and used as the salt water or salt water component of solutions containing salt water and salt water mixtures employed in the systems and methods discussed and shown herein. Such approximations of naturally occurring seawater may have a specific gravity of about 1.02 g/cm^3 to 1.03 g/cm^3, e.g., between about 1.020-1.024 or about 28-32 PPT, as read off of a hydrometer. A mixture of the above-identified sea salt mix having a specific gravity of about 1.026 g/cm^3 (as measured with a refractometer) was used in exemplary systems and methods. In the alternative, it is believed that actual seawater may be used in the systems and methods discussed and shown herein. The precise amount of salt in salt water or in the salt water component of the solutions containing salt water and salt water mixtures used and contemplated herein may vary from specific application to specific application.

[0117] In order to form both hydrogen and oxygen gas, salts capable of forming salt water mixtures that are useful for use in the electrolysis systems and electrolysis methods disclosed herein, should be water soluble salts and also should have a cation and an anion selected such that the cation has a lower standard electrode potential than H^+ and the anion has a greater standard electrode potential than OH^-. For example, the following cations have lower standard electrode potential than H^+ and are therefore suitable for use as electrolyte cations: Li^+, Rb^+, K^+, Cs^+, Ba^{2+}, Sr^{2+}, Ca^{2+}, Na^+, and Mg^{2+}. For example, a useful anion would be SO_4^{2-}, because it has a greater standard electrode potential than OH^- and is very difficult to oxidize. It is contemplated that Na_2SO_4 would be a useful salt for use with the electrolysis systems and methods disclosed here within because it is a water soluble salt that is composed of a cation (Na^+) that has a lower standard electrode potential than H^+ and an anion (SO_4^{2-}) that has a greater standard electrode potential than OH^-.

Additive

[0118] As previously indicated, as used herein an additive may be an organic, organometallic, or inorganic chemical compound having solubility, miscibility, or compatibility with salt water and solutions containing salt water and salt water mixtures (including seawater or solutions containing salt water and optionally containing at least one secondary fuel) and that is capable of altering the response of the salt water, various solutions containing salt water, and salt water mixtures in response to stimulation by RF energy. Both molecular and polymeric species are contemplated as being useful additives. It is further believe that useful amounts of additive include solutions containing salt water where the additive is present as at least one minor component in the solution containing salt water. Embodiments contemplated in this regard would include solutions containing salt water and having from about 0.001 to about 10.0 weight % additive, and more preferably from about 0.001 to about 1.0 weight % additive, and even more preferably from about 0.001 to about 0.1 weight % additive.

[0119] It is contemplated that a salt water solution or salt water mixture containing an additive will respond differently to RF stimulation versus comparable salt water solution or salt water mixture that does not contain any additive. We believe that the response of a salt water solution or salt water mixture to RF energy may be altered in a variety of ways. For example, an alteration in RF response that an additive may have may include but is not limited to increasing or decreasing the rate at which a solution or mixture containing the additive either heats, combusts, or both upon exposure to a fixed amount or flux of RF energy; exhibiting a desired temperature change or level of combustion of a salt water solution containing an additive with exposure to a larger or a smaller amount of RF energy; and decreasing the surface tension of a salt water solution containing an additive such that combustion of the salt water solution or mixture occurs upon application of an RF field without any need for externally perturbing the surface of the salt water solution. Surfactants, including soaps and detergents, are embodiments of useful additives in this regard since they are known to lower the surface tension of aqueous solutions. Furthermore, we believe that water soluble organic compounds that can lower the heat capacity of an aqueous solution or that can change the freezing point of water or that can form azeotropic mixtures with water would also be useful additives in this regard.

Secondary Fuels

[0120] As previously indicated, as used herein a secondary fuel may be any combustible organic compound that has solubility, miscibility, or compatibility with salt water or various solutions containing salt water or salt water mixtures (including seawater, salt water or solutions containing salt water that optionally contain at least one additive). It is believe that a useful amount of secondary fuel includes solutions containing salt water were the secondary fuel is present as the minor component. Alternatively, it is also believe that a useful amount of secondary fuel includes solutions containing salt or salt water were the secondary fuel is present as the major component. In this regard, embodiments are contemplated of salt water solutions containing from about 0.01 to about 99.99 weight % of at least one alternative fuel, and preferably from about 1.0 to about 99.0 weight % of at least one alternative fuel, and more preferably from about 10 to about 90 weight % of at least one alternative fuel, and even more preferably from about 30 to about 70 weight % of at least one alternative fuel, and even more preferably from about 40 to about 60 weight % of at least one alternative fuel.

[0121] It is contemplated that exposure to RF energy of a salt water solution containing at least one secondary fuel, wherein the secondary fuel is the minor constituent, may result in an enhancement or in a boost in performance in terms of the combustibility of the salt water solution versus the results obtained by a comparable salt water solution that does not contain any secondary fuel. Alternatively, it is also contemplated that exposure to RF energy of a salt water solution containing at least one secondary fuel, where the secondary fuel is the major constituent of the mix, allows RF energy to be used to combust the secondary fuel even though the secondary fuel itself may be RF inert. Without intending to be bound by theory, we believe that the secondary fuel may be useful as either the minor or the major component in a salt water solution because the salt water component of the salt water solution is stimulated by the RF signal and absorbs energy. As such, absorption of RF energy by the salt water component causes the temperature of the salt water solution to increase to the point where secondary fuel present in any amount volatilizes and becomes more capability of combusting in the presence of a spark, flame, or any other incendiary source. In this regard, methanol, ethanol, and iso-propanol are useful as secondary fuels because they are combustible organic solvents and are soluble with or have chemical compatibility with water. Furthermore, we believe that many additional organic solvents and compounds, which may have both volatility and solubility or miscibility with aqueous solutions, would also be useful as secondary fuels in this regard. For example, we contemplate that n-propanol, acetone, formaldehyde, acetic acid, and formic acid may also be useful secondary fuels.

RF Absorption Enhancers

[0122] Salt water, solutions containing salt water, and salt water mixtures may be processed using RF as-is. In the alternative, it is also believed that RF absorption enhancers may be added to the salt water, solutions containing salt water, and salt water mixtures prior to processing with RF to enhance the effects of the RF energy on the salt water, e.g., enhanced heating, enhanced, combustion, enhanced desalination, etc. The RF absorption enhancers may be particles made from RF absorbing materials that absorb one or more frequencies of an RF electromagnetic signal substantially more than other materials. This may permit the RF signal to heat salt water (or any solution containing salt water or salt water mixture) containing RF absorbing enhancers substantially more than it would salt water (or salt water solution or salt water mixture) that does not contain additional RF absorption enhancers.

[0123] Exemplary RF absorption enhancers include particles of electrically conductive material, such as silver, gold, copper, magnesium, iron, any of the other metals, and/or magnetic particles, or various combinations and permutations of gold, iron, any of the other metals, and/or magnetic particles. Examples of other RF absorption enhancers include: metal tubules (such as silver or gold nanotubes or silver or gold microtubes, which may be water-soluble), particles made of piezoelectric crystal (natural or synthetic), particles made of synthetic materials, particles made of biologic materials, robotic particles, particles made of man made applied materials, like organically modified silica (ORMOSIL) nanoparticles. Examples of yet other RF absorption enhancers that may be useful include RF absorbing carbon molecules and compounds: fullerenes (any of a class of closed hollow aromatic carbon compounds that are made up of twelve pentagonal and differing numbers of hexagonal faces), carbon nanotubes, other molecules or compounds having one or more graphene layers, and other RF-absorbing carbon molecules and compounds e.g., C60 (also known as a "buckyball" or a "buckminsterfullerene"), C70, C76, C84, buckytubes (single-walled carbon nanotubes, SWNTs), multi-walled carbon nanotubes (MWNTs), and other nano-sized or micro-sized carbon cage molecules and compounds. Such carbon-based particles may be in water-soluble form. Such carbon-based particles may have metal atoms (e.g., nickel atoms) integral therewith, which may affect their ability to absorb RF energy and heat in response thereto. Any of the foregoing (and subsequently listed) particles may be sized as so-called "nanoparticles" (microscopic particles whose size is measured in nanometers, e.g., 1-1000 nm) or sized as so-called "microparticles" (microscopic particles whose size is measured in micrometers, e.g., 1-1000 μm).

[0124] Additionally, RF absorbing carbon molecules and compounds may be fabricated as RF absorption enhancers to be particles with non-linear I-V characteristics (rectifying characteristics) and/or capacitance. Such non-linear I-V characteristics may result from, for example, nanotubes with a portion doped (e.g., by modulation doping) with a material giving n-type semiconducting properties adjacent a portion doped with p-type semiconducting properties to form a nanotube having an integral rectifying p-n junction. In the alternative, nanotubes can be fabricated with an integral Schottky barrier. In either case, it may be helpful to use nanotubes having at least two conducting regions with a rectifying region therebetween. Accordingly, rectifying circuits for RF absorbing particles for RF absorption enhancers may be fabricated from RF absorbing carbon molecules and compounds having non-linear I-V characteristics.

[0125] Any of the RF absorption enhancers described herein may be used alone or in virtually any combination of and/or permutation of any of the particle or particles described herein. For example, it may be beneficial to use a plurality of different RF absorbing particles described herein for purposes of tuning the reaction kinetics of the various methods herein described. Accordingly, virtually any combination or permutation of RF absorption enhancers may be used in virtually any combination of and/or permutation of any RF absorbing particle or particles described herein to create RF absorption enhancers for use in accordance with the teachings herein.

[0126] Of the RF absorption enhancers mentioned herein, some may be suitable for a 13.56 MHz RF signal, e.g., silver nanoparticles, gold nanoparticles, copper nanoparticles, magnesium nanoparticles, aqueous solutions of any of the metal sulfates mentioned herein, and RF absorbing carbon molecules and compounds. RF absorption enhancers using these RF absorbing particles are also expected to be effective at slightly higher frequencies, such as those having a frequency on the order of the second or third harmonics of 13.56 MHz.

RF Signal

[0127] The RF signals may have a frequency corresponding to a selected parameter of an RF enhancer, e.g., 13.56 MHz, 27.12 MHz, 915 MHz, 1.2 GHz. Several RF frequencies have been allocated for industrial, scientific, and medical (ISM) equipment, e.g.: 6.78 MHz±15.0 kHz; 13.56 MHz±7.0 kHz; 27.12 MHz±163.0 kHz; 40.68 MHz±20.0 kHz; 915 MHz±13.0 MHz; 2450 MHz±50.0 MHz. See Part 18 of Title 47 of the Code of Federal Regulations. These and other frequencies of the same orders of magnitude may be used in virtually any of the systems and methods discussed herein, depending on which RF absorbing particles are used. For example, RF signals having a fundamental frequency of about 700 MHz or less might be suitable for many of the systems and methods described herein. RF signals having a fundamental frequency in the high frequency (HF) range (3-30 MHz) of the RF range might be suitable for many of the systems and methods described herein. Similarly, RF signals having a fundamental frequency in the very high frequency (VHF) range (30-300 MHz) of the RF range might also be suitable for many of the systems and methods described herein. Of course, RF signals at any fundamental frequency may also have harmonic components that are multiples of the fundamental frequency of frequencies. Also, RF signals at any fundamental frequencies or periodic multiples of such fundamental frequencies that are harmonics of a fundamental frequency may be selected such that the frequency is the same as or has overlap with (either partially or completely) specific RF frequencies capable of stimulating or exciting any of the various electron energy levels of any of the various metal species that comprise the salts that are dissolved in the salt water solutions. For example, based on empirical testing we believe that an RF signal with a frequency of 13.56 MHz stimulates and/or excites Na ions better than any other ions herein so tested.

[0128] Additionally, in any of the embodiments discussed herein, the RF signal used may be a pulsed, modulated FM RF signal, or a pulse fixed frequency signal. A pulsed signal may permit a relatively higher peak-power level (e.g., a single "burst" pulse at 1000 Watts or more, or a 1000 Watt signal having a duty cycle of about 10% to about 25%) and may create higher local temperatures at RF absorption enhancer particles. Such pulsed signals may have any of various characteristics. For example, the RF pulse may be a square wave, or may be a sine wave, or may have a sharp rise time with an extended ringing effect at base line, or may have a slow rise time and a fast decay, etc. Pulsed RF signals (and other shaped RF signals) may produce very localized temperatures that are higher for a length of time on the order of about a millisecond or longer. For example, a short 5 kilowatt RF pulse of less than a second, e.g., on the order of microseconds (e.g., 3-4 microseconds) may be sufficient to raise the temperature of the mixture sufficiently to achieve the desired effect, e.g., combustion of the salt water, desalination, heating, creation of hydrogen gas, etc.

[0129] As discussed herein, the RF energy directed toward the salt water (or any solution containing salt water, or salt water mixture) may be RF energy having a very high field strength and may also be coupled through the portion of the reaction chamber with coupling heads having a very high Q (e.g., a Q on the order of 250 or more). A pulsed RF signal with a relatively higher power may be effective to quickly heat the salt water, etc., such as a pulse of BF or VHF RF energy (e.g., 27.12 MHz).

Rate of Combustion

[0130] Salt water combusts relatively quickly in a test tube using a 600 Watt 13.56 MHz RF signal. For example, sea water—natural or artificial—combusts in a test tube on the order of about 1 ml per minute initially and later combusts on the order of about 1 ml per every 30 seconds as a substantial amount of water has been combusted from the test tube. In some cases, less salt permits better combustion than more salt. For example, a mixture of 99.5% ethanol and 0.5% salt solution combusts much better (faster) than a 50/50 mixture of ethanol and salt solution (see examples below). As another example, sea water from the Gulf of Mexico combusted at about 2-3 ml per 90 second period at about 1000 watts, using either a 10 ml or 100 ml test tube, with the upper surface of the sea water in the RF field.

COMPARATIVE EXAMPLES

Series 1: Experiments with Ocean Water

[0131] It was previously demonstrated that salt water made from sea salt mix will combust using the RF system described in the '530 application. It has been confirmed that ocean water will combust using the ENI RF generator using the coupling circuit of FIGS. 46-49 of U.S. Provisional Patent Application Ser. No. 60/915,345, filed on May 1, 2007, and entitled Field Generator For Targeted Cell Ablation (Attorney Docket 30274/04036) ("the '345 application"), the entire disclosure of which is hereby incorporated by reference in its entirety, with a 6" silver coated circular copper Tx head (single plate) and a 9.5" silver coated square copper Rx head (single plate).

[0132] It is believed that the RF field that combusts salt water is substantially the same as the field discussed in the '345 application (see FIG. **53**—end of that application). (It is also believed that Ocean water will combust with the other head configurations discussed in the '530 application, as well.)

[0133] With respect to the combustion of ocean water, water from the Gulf of Mexico having the following characteristics was capable of being rapidly combusted with the above-described RF system (a 10 ml sample was analyzed prior to any combustion):

Parameter	Date of Analysis	Results	Units	Reporting Limit	Method
Bromide	May 10, 2007	57.0	mg/l	0.5	300.0
Calcium	May 11, 2007	970.0	mg/l	0.05	6010
Chloride	May 10, 2007	18552.0	mg/l	1.0	300.0
Fluoride	May 10, 2007	BRL	mg/l	0.1	300.0
Magnesium	May 11, 2007	1600.0	mg/l	0.5	6010
pH	May 9, 2007	8.02	s.u.@23.8 C.	0.01	EPA 150.1
Potassium	May 11, 2007	770.0	mg/l	0.1	6010
Sodium	May 16, 2007	12000.0	mg/l	1.0	6010
Sulfate	May 10, 2007	2633.0	mg/l	1.0	300.0

[0134] In this example, combusted ocean water differed from uncombusted ocean water in the concentration of most of these components increases, while the concentration of calcium decreases. Two 10 ml samples of the above water from the Gulf of Mexico were combusted down to 5 ml each and combined, and the resulting 10 ml of combusted ocean water was analyzed to reveal the following:

Bromide	May 10, 2007	57.0	mg/l	0.5	300.0
Calcium	May 11, 2007	730.0	mg/l	0.05	6010

[0135] A white residue forms on the inside of the test tube after combustion of salt water. The calcium may be part of that residue.

[0136] Using the above-described RF system, salt water will combust, as will solutions of HCl and NaCl. Distilled water will boil in the RF field, but will not combust. Adding additional sea salt mix (e.g., OCEANIC brand Natural Sea Salt Mix) to ocean water causes the rate of combustion to increase. Adding sea salt mix sufficient to approximately triple the sodium of ocean water causes a dramatic increase in the rate of combustion of the resulting salt water mixture. Thus, the methods herein may be modified by including the additional step of adding additional ions to the sea water prior to combustion.

[0137] Salt water (ocean water and/or salt water made from OCEANIC brand Natural Sea Salt Mix) will begin to combust in the above-described RF system at RF wattages of about 250 Watts and salt water will continue to combust at lower wattages, e.g., about 200 Watts, after igniting. Salt water may begin to combust spontaneously at higher temperatures, or may require some sort of igniter (e.g., a drop of salt water dropped through the RF field, which combusts and ignites the other salt water in the field). Additionally, some sort of wick (e.g., a piece of paper towel) extending above the surface of the salt water in the field will greatly increase the tendency of salt water in the RF field to spontaneously ignite. Filling the test tube to the brim with salt water and then adding a couple more drops of salt water facilitates ignition.

[0138] Using a setup with about 5.5" spacing between Tx plate and Rx plate, and the test tube being about 2" from the Tx plate at about the top of the Tx plate, and applying RF to the salt water, the products produced from exposure of salt water to RF energy burn. The temperature of the burning products of salt water exposed to RF energy has been measured as high as about 1700° C. using a FLIR Systems ThermaCAM P65 thermometer with ThermaCAM Quick View V2.0 Software, which measures temperatures up to 1700° C. (it is believed that the salt water is combusting at a higher temperature). Surprisingly, the temperature of the salt water in the test tube remains relatively low (e.g., less than 45° C.) while the salt water is combusting.

[0139] Without intending to be bound by this description, it is believed that the special RF field generated by the above-described RF system causes hydrogen in salt water to separate from oxygen, and then the hydrogen is burned in the presence of the released oxygen and the oxygen in the surrounding air.

[0140] Heat from RF-induced combustion of salt water may be used in any of the traditional methods of gathering and using heat, e.g., a heat exchanger, a Stirling Engine, a turbine system, etc.

[0141] Additionally, multiple Tx and Rx heads may be used at one or more frequencies.

Series 2: Experiments with Salt Water and Solutions with Additives and Secondary Fuels

[0142] For all the Series 2 examples described below, a circuit implementation of FIG. **16** was used to transmit the RF signal through the exemplary solutions to yield the various results. Unless otherwise indicated, for all examples a 13.56 MHz RF signal from an ENI OEM-12B RF generator having a variable power output of up to about 1000 Watts was applied for thirty seconds to the reaction chamber, which in these instances consisted of a glass test tube (in which the various exemplary solutions were placed) connected to a support arm that was positioned such that the test tube was suspended between the transmission head (one plate) and the reception head (three plates). Unless otherwise indicated, the salt water solutions used in carrying out the various examples included Gulf of Mexico salt water, Brine salt water extracted from an oil well (located in Erie, Pa.), and a 3.5 wt % stock solution of OCEANIC brand Natural Sea Salt Mix having a specific gravity of about 1.026 g/cm^3. For all examples containing ethanol, denatured, Apple Products® brand ethanol was used.

Salt Water

[0143] A first 100 mL sample containing salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the salt water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at about 300 Watts was then applied for about 30 seconds, after which the temperature was again measured using a fiber optic thermometer. Starting temperature=24.0° C.; Ending temperature=25.9° C.

[0144] A second 100 mL sample of salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the salt water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at about 600 Watts was then applied and, as soon as the RF signal was applied, combustion of the salt water was initiated by momentarily placing an ordinary steel screwdriver in contact with the lip of the test tube. The screw driver was removed and the RF signal was left on for about 30 seconds as combustion of the salt water continued. After about 30 seconds, the RF signal was turned off and the combustion of the salt water ceased. The temperature of the salt water sample was then measured using a fiber optic thermometer at both the top part of the test tube and the bottom part of the test tube. Starting temperature=20.5° C.; Ending temperature (Top)=66.0° C.; Ending temperature (Bottom)=28.0° C.

[0145] A third 100 mL sample of salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). However, the salt water used here contained 1 mL of stock salt water diluted to 100 mL with distilled water to give a 0.0035% salt water solution. A 13.56 MHz RF signal at about 600 Watts was then applied for about 30 seconds, after which the temperature was again measured using a fiber optic thermometer. Unlike the second sample of salt water, combustion of this third sample of salt water could not be initiated by placing an ordinary steel screwdriver in contact with the lip of the test tube. Starting temperature=26.6° C.; Ending temperature=75.5° C.

Salt Water+Carbonate and/or CO_2 (as the “Additive”)

[0146] Carbon dioxide may be useful as an additive, as may other additives that produce carbon dioxide. Photographs **9-11** of the incorporated material show the combustion of ground water—here a sample of brine water collected from an oil well (located in Erie, Pa.), while photograph **12** of the incorporated material shows the combustion of a sample of brine water obtained from the Gulf of Mexico. We have observed that the brine water obtained from the Gulf of Mexico combusts in a less sporadic manner than brine water collected from the oil well located in Erie, Pa. Without intending to be bound by theory, we believe high levels of carbonate salts present in the brine water collected from the oil well located in Erie, Pa., that is not present in the brine water collected from the Gulf of Mexico, effects the combustibility of the brine water collected from the oil well located in Erie, Pa. We further believe that, as the brine water collected from the oil well located in Erie, Pa. combusts carbonate salts that are present release carbon dioxide into the sample which acts to suppress or limit further combustion of the brine water as the RF signal is applied. Therefore, additional embodiments are contemplate wherein additives capable of inhibiting combustion or that are combustion suppressants may be added to any of the various salt water solutions herein disclosed in order to control or hinder the rate of salt water combustion or limit the amount of overall combustion.

Salt Water+Surfactant (as the “Additive”)

[0147] A 100 mL sample of salt water that also contained 1 metric drop (about 0.05 mL) of an ordinary hand soap (Liquid Nature Antibacterial Hand Soap) was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). A 13.56 MHz RF signal at about 600 Watts was then applied to the sample and as soon as the RF signal was applied, combustion of the salt water sample was initiated immediately. No external perturbation of the test tube (by a screwdriver, a drop of salt water, use of a wick or otherwise) was required. The RF signal was repeatedly switched on and off; each time the RF signal was switched on the salt water sample immediately began combusting, while each time the RF signal was switched off the salt water sample immediately ceased combusting.

Salt Water+Ethanol (as the “Secondary Fuel”)

[0148] A first 100 mL sample containing a mixture of 50 mL of ethanol and 50 mL of salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). A 13.56 MHz RF signal at several hundred Watts was then applied to the sample and, as soon as the RF signal was applied, combustion of the sample was initiated by momentarily placing an ordinary steel screwdriver in contact with the lip of the test tube. Once the RF signal was turned off the combustion of the sample ceased. Surprisingly, in the absence of any applied RF signal combustion of the sample could not be initiated even when an open flame was used to attempt initiation of combustion.

[0149] A second 100 mL sample containing a mixture of 99.5 mL of ethanol and 0.5 mL of salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the salt water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at several hundred Watts was then applied for about 15 seconds, after which the temperature was again measured using a fiber optic thermometer. Starting temperature=26.6° C.; Ending temperature=62.0° C. This example shows that an effective amount of salt (e.g., solid salt or a salt solution) can be added to enhance heating of liquids.

[0150] A third 100 mL sample containing a mixture of 99.5 mL of ethanol and 0.5 mL of salt water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the salt water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at several hundred Watts was then applied and, as soon as the RF signal was applied, combustion of the sample was initiated by momentarily placing an ordinary steel screwdriver in contact with the lip of the test tube. Combustion of the sample was highly energetic and resulted in a very large flame as compared to RF combustion of a stock solution of salt water that did not contain any ethanol. The screw driver was removed and the RF signal was left on for 15 seconds as energetic combustion of the sample continued. Combustion was so energetic that some of the sample solution bubbled out of the test tube and onto the laboratory floor when it continued to combust. After about 15 seconds, the RF signal was turned off. However, combustion of the sample did not cease and the sample had to be extinguished using a fire extinguisher.

Control **1**: Distilled Water

[0151] A 100 mL sample containing distilled water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the distilled water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at about 300 Watts was then applied for about 30 seconds, after which the temperature was again measured using a fiber optic thermometer. Starting temperature=24.0° C.; Ending temperature=24.8° C.

Control **2**: Tap Water

[0152] A 100 mL sample containing ordinary tap water was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the ordinary tap water was measured using a fiber optic thermometer. A 13.56 MHz RF signal at about 300 Watts was then applied for about 30 seconds, after which the temperature was again measured using a fiber optic thermometer. Starting temperature=23.7° C.; Ending temperature=47.8° C.

Control **3**: 100% Ethanol

[0153] A 100 mL sample containing ethanol was placed in a test tube and the test tube was then attached to a support arm and positioned between the transmission head and receiver head of the RF apparatus (described above). The temperature of the ethanol was measured using a fiber optic thermometer. A 13.56 MHz RF signal at several hundred Watts was then applied for about 15 seconds, after which the temperature was again measured using a fiber optic thermometer. Starting temperature=25.0° C.; Ending temperature=30.0° C.

Dissociation of Water

[0154] In his earlier patent documents, inventor John Kanzius describes a process in which liquid water is dissociated into hydrogen and oxygen using an external RF field. For convenience, this process is referred to in the following paragraphs as the "electromagnetic dissociation of water." Normally, the electromagnetic radiation is in the form of an RF field generated between a transmission head and a reception head external to the water being dissociated. These earlier patent Kanzius documents also describe various systems and methods for electromagnetic dissociation of water with an external RF field generated by any of various RF systems which may be referred to as Kanzius RF transmitters or Kanzius RF generators.

[0155] In conventional electrolysis of water, a direct electrical current in passed through water between two electrodes immersed in the water. At the negatively charged electrode, the cathode, water is reduced according to the following half cell reaction:

$$2H_2O+2e^-\rightarrow H_2+2OH^-,$$

[0156] thereby liberating hydrogen gas. At the positively charged electrode, or anode, water is oxidized according to the following half cell reaction:

$$2H_2O\rightarrow O_2+4H^++4e^-,$$

[0157] thereby liberating oxygen gas.

[0158] In the Kanzius electromagnetic dissociation of water, it is believed that the same reactions are occurring, i.e., the dissociation of water into hydrogen and oxygen. However, in the electromagnetic dissociation of water, these reactions occur in response to applied electromagnetic radiation only. Thus, the electromagnetic dissociation of water differs from conventional electrolysis of water in that, in the electromagnetic dissociation of water, alternating electrical energy is applied without electrodes as opposed to applying direct electrical energy with electrodes. Similarly, the electromagnetic dissociation of water differs from other techniques for the direct application of electrical energy such as microwave heating in that, in the electromagnetic dissociation of water, the applied electrical energy causes water in the liquid phase to dissociate into its component parts without substantial heating. In contrast, microwave heating causes substantial heating and eventual evaporation, and is not known to cause direct dissociation of water. The electromagnetic dissociation of water also differs from known techniques for the thermal decomposition (thermolysis) of water which occur in the vapor phase at very high temperatures, with the energy needed for causing the reaction to occur being supplied by conventional heating (e.g., conduction or convection) as opposed to irradiation with electromagnetic radiation. Note, also, that in the Kanzius electromagnetic dissociation of water (as well as the other RF treatments described in this disclosure), no additional energy input such as applied audio signal or an external magnetic field need be applied, and indeed is not normally used.

Electrolytes

[0159] Electrolysis of pure water is impossible to carry out, as a practical matter, because the electrical conductivity of pure water is too low. Therefore an electrolyte, i.e., a substance capable of increasing the electrical conductivity of the water, is added. Ionizable salts are most commonly used for this purpose, the salt chosen normally having a cation with a lower standard electrode potential than H^+ and an anion with a higher standard electrode potential than OH^-.

[0160] In the electromagnetic dissociation of water, the same additives useful for facilitating conventional electrolysis of water can be included in the water being dissociated here. Thus, any additive capable of increasing the electrical conductivity of water can be added. Many of these additives are described above and in John Kanzius' prior patent documents. For example, this additive may be an ionizable salt having a cation selected from Groups I, II and III of the Periodic Table, as described above, more commonly Groups IA, IIA and IIIA. Essentially any anion capable of producing a soluble salt from such cations can be used, examples of which include chlorides, bromides, fluorides, other halides, nitrates, sulfates, acetates, carbonates, phosphates, carboxylates, sulfates, sulfonates, anions of other organic acids (e.g., acrylates, methacrylates, any other C_3-C_{12} organic acid, etc.) can be used. Specific examples include NaCl, NaBr, NaF, Na2SO4, NaNO3, Na2(PO4), Na-acetate etc.

[0161] Similarly, soluble metal salts and complexes of transition metals such as Cr, Mo, W, Cu, Co, Ni, Fe, Cd, etc. can also be used.

[0162] In addition to ionizable salts, other materials can be used as an electrolyte for fostering the electromagnetic dissociation of water, provided they are used in appropriate amounts. For example, as illustrated in the following working examples, aqueous colloidal dispersions of silver particles containing up to about 200 ppm silver readily combusted when irradiated with electromagnetic radiation in accordance with this invention, at least under the particular conditions tried in these examples. Similar colloidal dispersions containing more than about 200 ppm silver did not readily combust, which is believed due to the fact the silver in these colloids had settled out of dispersion as confirmed by visual inspection.

[0163] In addition to silver, it is believed that dispersions of other electrically conductive particles will also foster the electromagnetic dissociation of water in accordance with this invention-again, provided they are used in appropriate amounts. Examples of materials which can be used to form such electrically conductive particles include metals, e.g., Cu, Ag, Zn, semi-conductive materials such as TiO_2, ZrO_2, etc., carbon in various forms such as graphite, activated carbon black, etc., and so forth.

[0164] In addition to ionizable salts and electrically conductive colloids, still other materials can be used to increase the electrical conductivity of the water being electromagnetically dissociated according to this invention. For example, hydroxyethyl cellulose when added to water in an amount sufficient to produce a gel has been found to foster this electromagnetic dissociation, at least under the conditions used in the following working examples. In addition, various other oxygen and nitrogen-containing organic compounds such as oxalic acid, L-alanine, polyvinyl alcohol, ethyl acetate, ethylene glycol, glycerol, methanol, ethanol and propanol have also been found to foster this electromagnetic dissociation, provided they are used in suitable amounts under appropriate conditions.

[0165] In contrast, similar oxygen and nitrogen-containing organic compounds such as formic acid, acetic acid, lauric acid and salicylic acid were found not to foster this electromagnetic dissociation, at least under these same conditions. In the same way, many inorganic materials which do not readily ionize were also found not to foster this electromagnetic dissociation, at least under these same conditions. Examples include boric acid, MS Type 5 Zeolite, quartz, Na-montmorillonite, Ca-montmorillonite, CabOSil (untreated fumed sub-micronometer silica), Plaster of Paris, Kaolinite and Hydrotalcite. All of this merely indicates that, in order to function as an effective electrolyte, an additive needs to have a combination of properties including sufficient solubility in water, effect on the hydrogen/oxygen bond strength of water and other factors so that a not-insignificant increase in the electrical conductivity of water is achieved when the additive is added.

[0166] The concentration of the electrolyte included in the water to be electromagnetically dissociated according to this invention is not critical and essentially any amount can be used so long as the electrical conductivity of the solution or dispersion obtained is increased. For ionizable salts, typical amounts include enough to produce solutions which are at least about 0.2 molar up to saturation (for example, for sodium chloride, aqueous solutions of from about 0.3% to about 3% to about 30% combusted, as shown in the working examples, below). For colloidal dispersions of electrically conductive particles, amounts as low as 10 ppm can be used, while concentrations on the order of 20 to 800 ppm, or more especially 30 to 500 ppm, are more typical. For hydroxy ethyl cellulose and its hydroxy C_1-C_{12} alkyl analogs, essentially the same amounts can be used although amounts suitable for creating a gel are desirable. Greater concentrations of these additives can also be used, since these additives will still impart their electrical conductivity-increasing effect even if present in greater than saturation amounts.

[0167] In this connection, it is believed that this aspect of the invention in which water is electromagnetically dissociated will occur in any composition containing free water (i.e., water which is not chemically combined) even if substantial amounts of other ingredients are also present. So, for example, even moist powders can be electromagnetically dissociated, it is believed, since immersion of electrodes in the water being dissociated is unnecessary.

[0168] Similarly, it is also believed that concentration of the electrolyte to be included in the water to be electromagnetically dissociated in particular embodiments of this invention also depends on the intensity of the electromagnetic radiation used for the irradiation. As can be seen from the following working examples, some samples showed little or no evidence of dissociation (as reflected by the generation of a combustible gas) when irradiated under the standard conditions used in these examples (600 watts) but did show significant evidence of dissociation when irradiated at higher power levels, e.g., 800 watts or 1000 watts. Accordingly, it should be appreciated that the concentration of the electrolyte to be used in particular embodiments of the electromagnetic dissociation process of this invention depends not only the identity of the particular electrolyte employed but also on the particular irradiations conditions employed as well. These particulars—e.g., the power(s) (and wavelength(s)) of RF signal, the location in the field, and the amount of time of each RF signal transmission, and number of times, needed for effective electromagnetic dissociation of water, or to obtain a desired change result or change in properties of the substances disclosed herein, such as combustion or a shift in Raman spectrum or change in XRD data—can be easily determined by those of ordinary skill in the art by routine experimentation using the teachings in the earlier Kanzius patent documents, and the teachings herein.

[0169] Still other aqueous materials that can be electromagnetically dissociated in accordance with this aspect of the invention are the so-called "structured waters," i.e., microwave distilled deionized water, occasionally referred to as "Sedlmayr" water. See the following patent documents: U.S. Pat. No. 7,119,312 B2; WO 08020912 A2; US 2007/0095823 A1; US 2006/0289502 A1; US 2006/0006172 A1 and US 2006/0006171 A1.

Non-Aqueous Materials

[0170] In another application of this invention, "non-aqueous" materials are heated by the application of radio frequency electromagnetic radiation, or "RF energy," i.e., electromagnetic radiation having a lower frequency and a higher wavelength than microwave energy. In this context, "non-aqueous" means compositions in which the water content is so low that electromagnetic dissociation of water will not occur to any significant degree when the composition is irradiated with the RF energy.

[0171] Microwave radiation is commonly accepted to have a wave length of less than 1 meter (<1 M) to greater than 1 millimeter (>1 mm) and a corresponding frequency of 300 MHz (3×10^8 Hz) to 300 GHz (3×10^{11} Hz). Electromagnetic radiation having wave lengths shorter than 1 millimeter and corresponding frequencies greater than 300 GHz is generally opaque to the atmosphere until the atmosphere becomes transparent again in the infrared and optical window frequency ranges. Electromagnetic radiation having wave lengths longer than 1 meter and corresponding frequencies less than 300 MHz is generally regarded as "radio frequency" electromagnetic radiation or "RF energy." In accordance with this aspect of the invention, RF energy is used to heat a wide variety of different non-aqueous materials. RF signals having a fundamental frequency of about 250 MHz or less, 200 MHz or less, 150 MHz or less, 100 MHz or less, or even 50 MHz or less, are even more interesting. RF signals having a fundamental frequency in the high frequency (HF) range (3-30 MHz) of the RF range are especially interesting, since living tissue is virtually transparent to RF signals in this range. RF signals in the VHF range (30-300 MHz) are also of interest. Most commonly, the frequencies of such signals will not be below about 2 MHz, although frequencies in the medium frequency (MF) range (3 MHz-300 kHz) and even the low frequency (LF) range (300 kHz-30 kHz) are contemplated. It will be appreciated that these frequencies can also be used in connection with the electromagnetic dissociation of water as described above.

[0172] The various frequencies for the Kanzius RF transmitter and the associated methods can be characterized in terms of electron volts (eV): e.g., 3 MHz RF energy may be characterized as photons of 1.24×10^{-8} eV; 13.56 MHz RF energy may be characterized as photons of 5.6×10^{-8} eV; 30 MHz RF energy may be characterized as photons of 1.24×10^{-7} eV; and 300 MHz RF energy may be characterized as photons of 1.24×10^{-6} eV. Thus, the Kanzius RF transmitter may be further characterized as an RF transmitter (e.g., any of the configurations and/or characterizations herein such as those directly shown herein and those incorporated herein by reference) that generates low-energy photons (e.g., any one or more of the following: photons on the order of 10^{-8} eV, or less than 10^{-7} eV, or less than 10^{-6} eV, or less than 10^{-5} eV, or 5.6×10^{-8} eV, or $5\frac{1}{2}\times10^{-8}$ eV, or 1.24×10^{-8}–1.24×10^{-7} eV, or 1.24×10^{-8}–1.24×10^{-6} eV, or 1.24×10^{-8}–1.24×10^{-6} eV, or "about" any of these) that are capable of electromagnetic dissociation of water in various aqueous solutions and/or aqueous suspensions and/or aqueous pastes (and the other non-aqueous substances described herein) without requiring any additional energy input such as an external audio signal or an external magnetic field or current via electrodes. This is, indeed, remarkable since the H—OH bond energy is 5.2 eV.

[0173] One type of non-aqueous material that can be heated in this way are organic compounds (liquids, solids and gases), particularly those substituted with oxygen, nitrogen and/or sulfur. For example, various oxygen-containing organic liquids such as organic acids, esters, ketones, aldehydes, alcohols, glycols, carbonates, epoxides, furans, and derivatives, etc. can be heated in this way. Indeed, it is believed that any organic compound containing an —OH radical can be heated in this way. Similarly, various nitrogen containing organic liquids such as amides, amines, amino acids, as well as DNA, RNA and other "nucleic acid related compounds." In this context, "nucleic acid related compound" means ribonucleic acid compounds ("RNA") and deoxyribonucleic acid compounds ("DNA"), as well as the nucleotides, nucleosides and heterocyclic amine bases which are the nitrogen-containing precursors of or decomposition products of these RNA and DNA compounds, and mixtures of these compounds. See, for example, pages 1107-1149 of Organic Chemistry, 3rd Edition, by John MaMummy, Brooks/Cole Publishing Company, 1992; Lehninger, Biochemistry, Second Edition, Worth Publishers, Inc., pp. 729-747, © 1975; as well as King et al., Chemistry of Nucleic Acids, Version May 11, 2002, available on the web at http://www.med.unibs.it/~marchesi/nucleic.html.

[0174] Naturally occurring cellulosic materials such as plant leaves, bark, wood, etc. can also be heated. In addition, various carbonaceous materials such as coal, shale oil shale, tar sands, etc., can also be heated.

[0175] Another type of non-aqueous material that can be heated in accordance with this invention are inorganic solid materials. For example essentially any mineral, especially those containing combined oxygen, can be heated in this way. Examples include various clays, zeolites, silicas, aluminas and aluminosilicates, e.g., brucite, gibbsite, quartz, bauxite, etc. In addition to naturally occurring minerals, essentially any type of refined inorganic compound (i.e., a compound produced by purifying a naturally occurring mineral) as well as man made inorganic compounds, can be heated to a greater or lesser extent by the RF heating technology of this invention. For example, salts, oxides, bases, oxide complexes such as transition metal complexes, and so forth can be heated.

[0176] Another interesting phenomenon achieved by the present invention, at least in some embodiments, is a chemical and/or phase change in the non-aqueous material being irradiated as reflected by a change in its X-ray diffraction pattern. In some instances, such as in the case of hydroxyethyl cellulose both in solid form and contained in water, analysis by Raman Spectroscopy shows that an actual chemical change in the sample occurred, as reflected by a change in the characteristic peaks of its X-ray diffraction pattern. In other instances, only the relative intensities of certain peaks changed, thereby indicating a change in state (e.g., a change in crystal structure) but not a change in chemical identity. Due to the preliminary nature of this work, no conclusions can be drawn at this time other than noting that, at least in some instances, the application of RF energy in accordance with this aspect of the invention is sufficiently intense and powerful to effect a change in state of the non-aqueous materials being treated.

WORKING EXAMPLES

[0177] In order to more thoroughly describe this invention, the following working examples are provided:

Part 1: Liquid Samples

[0178] Liquid samples were suspended in a test tube of standard size and volume in the RF field positioned off-center as shown in the photographs (exact measurement of the position was not determined and there was some play in the exact location, however it was always closer to the coupler). Because the goal was to learn what would or would not combust, little attention has been placed on threshold RF power values, and RF power values were not recorded for a number of samples. Even if the RF values were recorded, those values generally reflect the standard instrument configuration at which the sample was tested and so all that can be ascertained from their values is that Sample X did or did not combust well at that power. In general, if certain samples failed to combust, the power was increased until the threshold for combustion was attained.

[0179] Unless otherwise noted, all flames self-extinguished upon turning off the RF field. Those that sustained a flame with the field off were snuffed out with a flame-proof mitt.

[0180] Unless otherwise noted, all sample solutions in water were prepared with the de-ionized (DI) water. Most solutions were tested at 3% concentration (as specified in the table). Dilute acid solutions were prepared using 8 drops of the pure acid in the test tube to which DI water was added to fill the tube. All samples were run in standard Pyrex test tubes (tt) unless otherwise noted. Teflon (PTFE) test tubes and Quartz (Q) test tubes were used as noted. The following results were obtained:

TABLE 1

Liquid Samples

Sample Description, holder	RF power	Observations [C = combusts]
GROUP 1 SALTS- THE SODIUM SERIES		
0.3% NaCl in DI water		C,
3% NaCl in DI water		C,
3% NaCl in DI water, PTFE tt		C,
3% NaCl in DI water, Q tt		C,
3% NaCl in DI water, pyrex tt	600 W	C,
30% NaCl in DI water		C
3% NaF in DI water	600 W	C
3% NaBr in DI water	600 W	C
3% NaNO3 in DI water	600 W	C, cracked tt

Pure DI water (control)		No combustion
Tap water from PSU MRL	Up to 800	No combustion, but getting ready to boil
MISCELLANEOUS		
Quartz solution	600 W	No combustion
Carbon black in 3% NaCl	600 W	C, but sparked and crackled quite a bit
OTHER INORGANICS		
3% NaOH		C
<3% NH4OH	Up to 800	No combustion
3% NH4(CO3)	600 W	C
3% NH4Cl	600 W	C
ORGANICS		
D-Glucose		C, weakly at higher RF power
Sucrose		
Formic Acid		No combustion, but boiled over
Acetic Acid, in mini tt holder		Inconclusive. No combustion, but realized mini-holder may have been located too far up and out of the active field area; NaCl in same holder and location did not ignite

TABLE 1-continued

	Liquid Samples	
Sample Description, holder	RF power	Observations [C = combusts]
Acetic Acid		No combustion
Citric acid diammonium salt		*see solid samples data below*
Laurie Acid		*see solid samples data below*
Oxalic Acid		C, cracked tt
Salicylic Acid solution	600 W	No combustion - expanded up and nearly oozed out of the tt
2-Methoxycrotonic acid		*see solid samples data below*
3% L-Alanine in DI water	800 W	C, but had trouble igniting at lower power; faint flame
Poly-vinyl Alcohol solution	1200 W	C
Poly-vinyl alcohol, PTFE tt		No combustion but boiled over after field was turned off
Ethylene Acetate		C; sustains burn after field is off
Ethylene Glycol		No combustion - though it almost ignites
Ethylene Glycol	1000 W	C
Glycerol		C after increasing RF power; sustained flame after field turned off
Methanol	1000 W	C, just barely . . . low thin flame
Ethanol	0 W	EtOH combustion while adding drops of 3% NaCl
2-Propanol		C
Acetone	600 W+	C, Intensity of flame increases with RF power increase
n-decane	~1000 W	No combustion
Dodecane	~1000 W	No combustion
LAYERED INORGANICS		
CabOSil		C
CabOSil, PTFE tt		C
COLLOIDAL SILVERS		
ABL's start water*	800 W	C
ABL 10 ppm Ag	800 W	C
ABL 22 ppm Ag	800 W	C
ABL 32 ppm Ag	800 W	C
ABL 200 ppm Ag	High power	C but flame does not sustain
ABL 200 ppm Ag	800 W	No combustion, but boiled over, No combustion, Note that sample bottle showed silver settled to the bottom and hence the sample may not be considered as a colloid hence inconclusive data.
ABL 400 ppm Ag	800 W	No combustion, Note that sample bottle showed silver settled to the bottom and hence the sample may not be considered as a colloid hence inconclusive data.
ABL 200 ppm Ag, PTFE tt		C, but not sustained . . . then flame went out and it boiled over
ABL 410 ppm Ag, PTFE tt		No combustion, but overflowed from nearly boiling and turned brownish
GR water w 20 ppm Ag	1000 W	C
GR water w 32 ppm Ag	1000 W	C
GR water w Zinc colloid	1000 W	C

*"ABL" refers to reverse osmosis water from American Biotech Laboratories
**GR" refers to reverse osmosis water from General Resonance Corp.

Part 2: Solid Samples

[0181] Irradiation of the solid samples identified in the following Table 2 with Code A was done with the sample contained in a mini-holder having 5 ml volume capacity. After a series of runs on the first few samples, it was determined that this arrangement was not optimal, and so we conclude that most of this data is less than reliable. Nonetheless, it is reported here for the sake of completeness.

[0182] Irradiation of the solid samples identified in the following Table 2 with Code B was done using a standard ceramic crucible to hold the powder and pellet samples. A temperature sensor was dipped into the samples to register their temperature changes. All of the samples were positioned and run identically at 600 watts RF power for 2 minutes each, and their temperature rises were recorded. Sample mass varied—most of the time the crucible was filled ¾ of the way, but there were a few samples for which there was only a very small amount, so data was taken on what was available. Nonetheless, this data is believed to be more reliable, as the object of these experiments was only to discern gross effects.

[0183] Additional structural data from Raman spectroscopy and x-ray diffraction analysis of select samples is presented in the Attachment hereto. The following results were obtained

TABLE 2

Solid Samples

Sample Description, holder	Code	RF power	Observations [C = combusts]
INORGANICS			
Mg(OH)2	A		No combustion
Ca(OH)2	A		No combustion
Al(OH)3	A		No combustion. T went upto 170 F.
AlOOH. *x*H2O	A		No combustion. Temperature up with field on; field off at T = 122 F.
ORGANICS			
D-Glucose (anhydrous) dry	A		No combustion. Slow temperature rise; T = 77 F. at field off
Sucrose	A		No combustion. Temperature rose slowly with the field on: T = 76 F. at field off
Citric acid diammonium salt	A		No combustion. Slow temperature rise; T = 74 F. at field off
Na-oxalate, mini holder	A		No combustion. VERY slow rise in temperature
L-2-Alanine	A		No combustion
Poly-vinyl alcohol	A		No combustion
LAYERED INORGANICS			
Na-Montmorillonite	A		No combustion.
Ca-Montmorillonite	A		No combustion.
CabOSil	A		No combustion.
Plaster of Paris	A		No combustion.
Kaolinite	A		No combustion.
Hydrotalcite	A		No combustion.
Al2O3	B		T rises upto 97.4° C. in 2 min
Y2O3	B		No significant temp rise
Hydroxyl ethyl cellulose	B		T rises upto 89.9° C. in 2 min
LaPO4: Ce, Tb	B		T, Peaked upto 210° C. in 1.30 min then drops to 180 C.
CuO	B		T rises upto 111° C. in 2 min
B4C	B		Slow increase up to 39.7° C.
Crystalline silica	B		Slow increase up to 28° C.
Cellulose from crashed leaf	B		Slow increase up to 42.2° C.
Lead Manganese Niobate pellet	B		Slow increase up to 27° C.
LiNbOS pellet	B		Slow increase up to 27.8° C.
Doped ZnS, EL blend	B		Slow increase up to 30.8° C.

[0184] Additional structural data from x-ray diffraction analyses of selected samples subjected to RF irradiation according to this invention, as well as photographs showing combustion of the gas product generated by the electromagnetic dissociation of water in accordance with this invention, are shown in FIGS. **27-36**.

[0185] FIG. **27** shows that water containing a variety of different sodium salts, when electromagnetically dissociated according to this invention, produces a gas product that readily combusts.

[0186] FIG. **28** shows the same result occurring with water containing a variety of different transition metal salts.

[0187] FIG. **29** shows an XRD pattern on hydroxyethyl cellulose irradiated with RF energy in accordance with this invention, both before and after irradiation.

[0188] FIG. **30** is a view similar to FIGS. **1** and **2** showing that water containing phosphoric acid also produces a combustible product gas when subjected to RF energy in accordance with this invention.

[0189] FIG. **31** illustrates UV-VIS spectra of a group of aqueous colloidal silver samples containing different amounts of silver, both before and after irradiation.

[0190] FIG. **32**, which is an emission spectra of $SrCl_2$ in DI water, indicates that combustible H2 gas has been produced.

[0191] FIG. **33** illustrates the self ignition of salt water droplets in an RF field of this invention. Water droplets containing many other electrolytes described above also self combusts in this way.

[0192] FIG. **34** shows that structured water produced according to U.S. Pat. No. 7,119,312 of Steve Sedlayer also readily combusts when subjected to RF energy in accordance with this invention.

[0193] FIG. **35** shows the Raman Spectra of an NaCl-containing sample irradiated with RF energy in accordance with this invention, both before and after irradiation.

[0194] These figures further illustrate that irradiation with RF energy in accordance with this invention produces a significant change in the materials being irradiated.

[0195] Although only a few embodiments have been described above, many changes and additions can be made without departing from the spirit and scope of the invention. All such embodiments are intended to be included within the scope of the present invention.

A breadboard Audio Amplifier

Back to Radio..

A little project stemming from my persistant difficulty in hearing. (Losing one's hearing is never fun to admit, but combined with crystal radio, well, its trouble!) I hope I do not offend any "purists" with this project. Still, I understand that many crystal radio owners keep a small amplifier too, for "those times" when, well, you know.. So, this amplifier project, its for, well, those times.. (I suspect Radio Shack would have discontinued their nifty Mini Amplifier years ago had it not been for the crystal radio community.)

My idea was to build my own unit rather than use a store-bought amplifier. Additionally, I wished to put my own stamp on it, make it unique. I started with a kit for the basic layout and electronics. I wanted to base things on the NI LM386 chip which is a good part and hard to break. I found several distributers of what appears to me as the exact same kit and so chose the cheapest $6 dollar kit. NI sells the LM386 for 34 cents a pop and would even provide a few "samples" but then I would be stuck laying things out and wireing.. Been there, done that. A printed circuit board is just SO much easier to use.

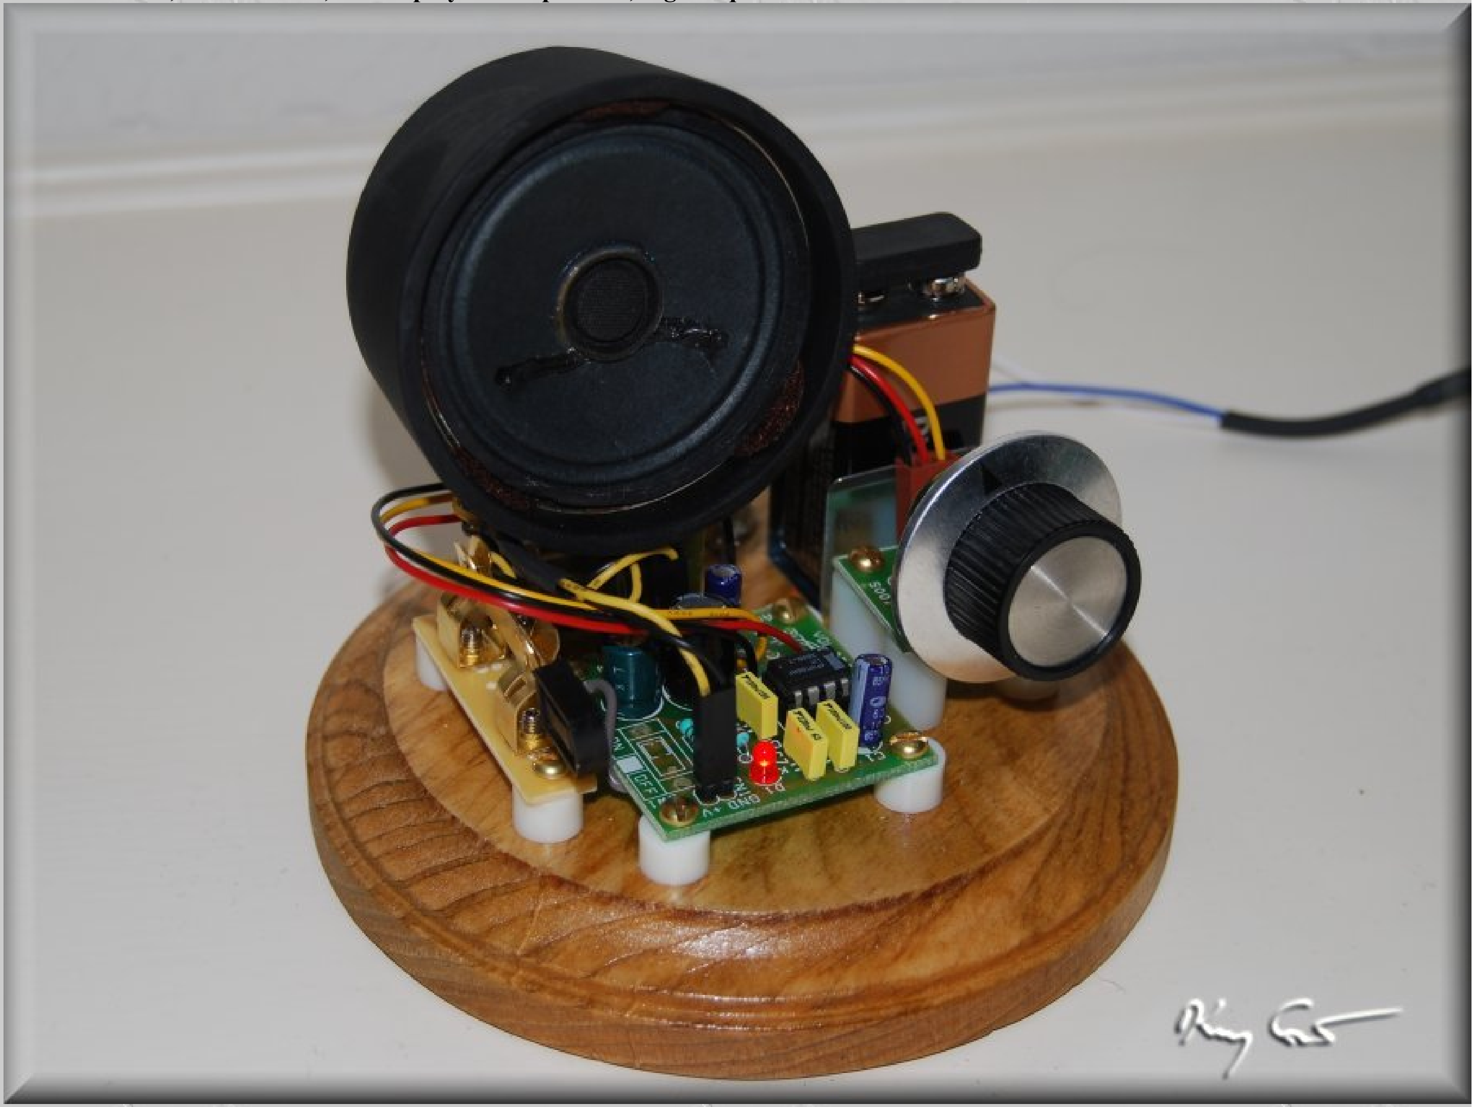
One of my inspirations for this project also stems from the nature of modern electronics in general, and the Radio Shack mini amplifier in partictular. Using my RS mini, I am always struck by the contrast between electronics new and old. With crystal radios one builds with passion, creating something more than a mere radio, but a work of art, a piece of furniture. Still, the technology itself is primitive dating back to the dawn of radio. When I look at the mini amplifier, it looks like a toy yet inside there is the most wonderful technology, solid state integrated circuitry. We take this advanced technology and slap it inside a cheap plastic box, an appliance. Naturally, I don't complain about the price, but for my project I wish for something above.

The solution struck me as obvious, give the same care and respect for the amplifier as I do the radio. I also sought to maintain a "vintage" visual aspect for the unit, breadboard layout, antique binding posts and a large adequate volume control knob, (the pitiful volume control wheel on my RS mini has already come apart once and threatens to break at any time). I wanted a nice lacquered base and sturdy speaker enclosure. The enclosure was the main challenge. I finally ended up with a heavy plactic goblet from a local thrift shop cut down to a tapered cylinder into which the speaker can be placed tightly. The rest of the set is modular with plug-in connections for the audio in, power, speaker, and volume control potentiometer. A question, do I add a brass knife switch for the on-off? I worry I am out of room on the base. Still pondering this.

I was initially worried that the audio input impedance may cause me trouble. I read so much about this, impedance matching, transformers, etc etc, almost a fetish really. I have subsequently learned that the LM386 input impedance is about 800 Megohms, the 10k pot being the limiting factor. So, with considerable relief, I concluded this ought not present any problems with the crystal radio circuits. I find the amplifier works very nicely with my radios. The sound is as good as the Radio Shack unit.

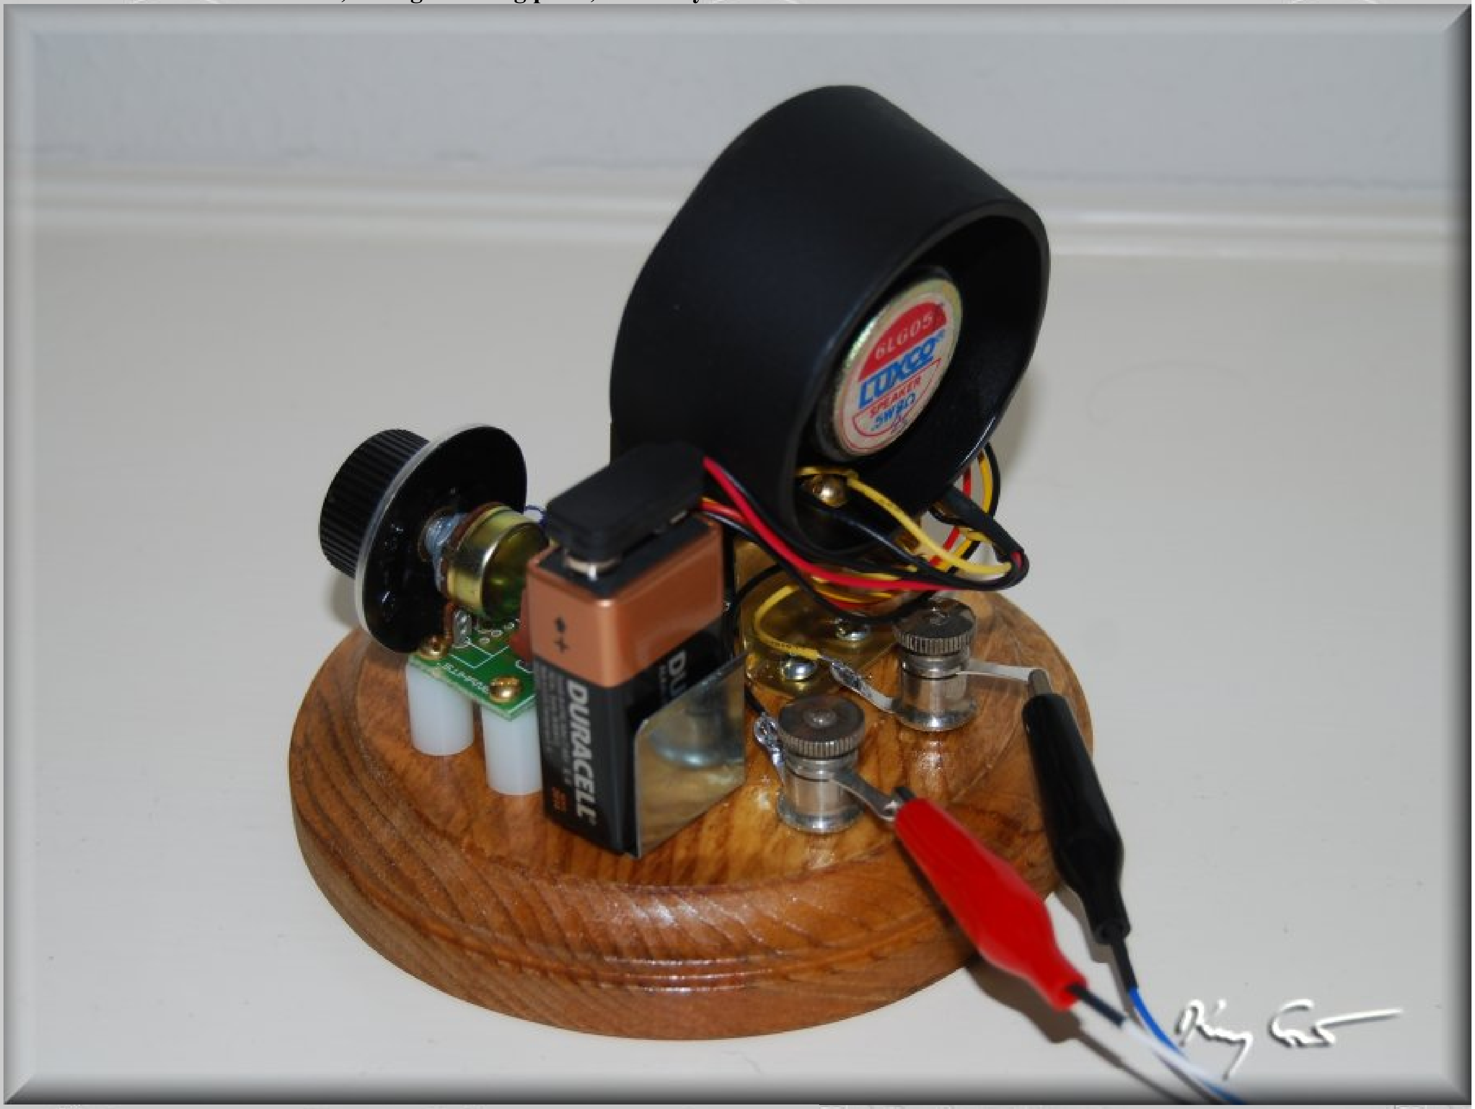
The amplifier certainly adds to the vintage "look" of my setup. Well, you be the judge, I hope I come close, please check out the photos...

From the front, wooden base, full display of components, big adequate volume control..



[illegible]

It even looks nice from behind, vintage binding posts, naturally..



Schematic of the kit, (AnyKits.com) A005. The kit is configured with a maximum gain between 45 and 50, too high for headphones but too low really for listening with the speaker easily. You will note the location of R1 (in series with a 10uF capacitor) between pins 1 and 8 on the LM386. If you short the resistor leaving only the capacitor, then the gain will increase to the maximum of 200. If you do such a project, I recommend you download the LM386 datasheet from National Instruments.

Part II: Diode Test Data Report

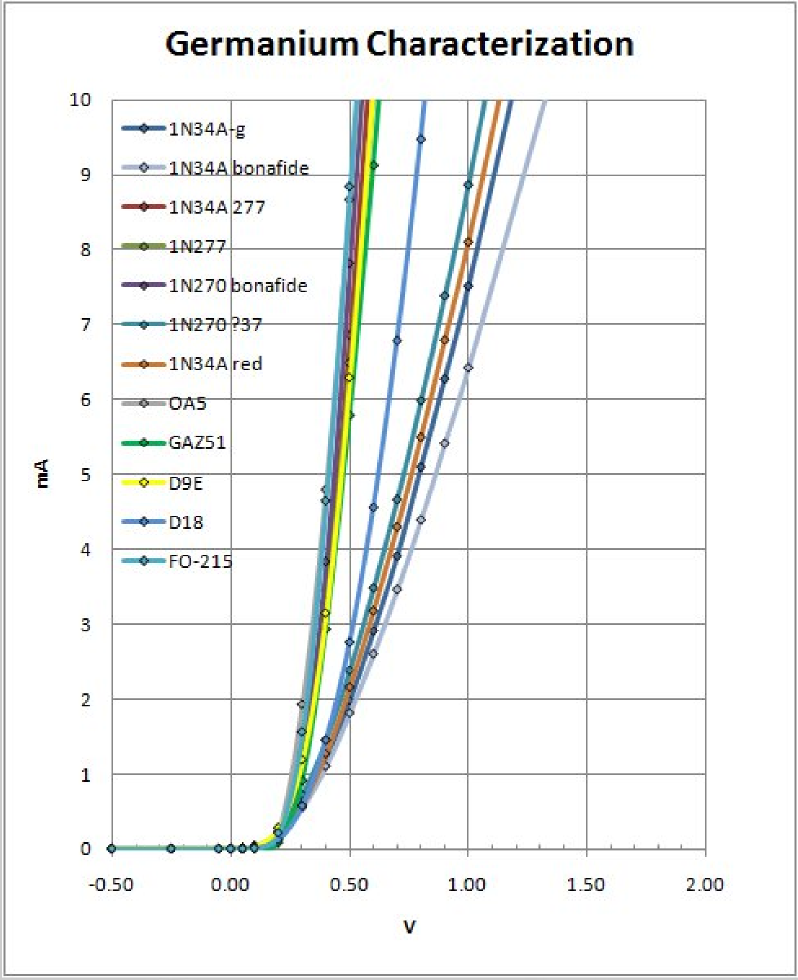
Back to Lab..

Test Results

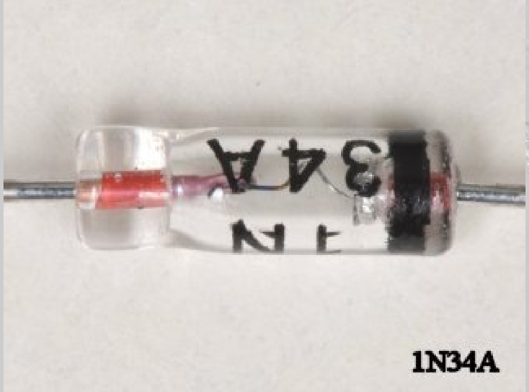
Over a period of several weeks in 2013 I ran I-V characterization measurements on a good number and variety of diodes, crystals and my two tubes to see how very thing stacks up. The following presents the resulting curves, diode photos, and some puzzling questions/conclusions I churned up in the process. These Characteristic Curves carry the voltage out to 2.0 Volts, well beyond any signal strength one might expect to receive with a crystal set. This is important to note because the curves themselves are dominated by the diode series resistance. After each discussion I then include my spreadsheet with the detail DX-level analyses that provide the critical information about diode "n", (Ideality factor) "Is", (Reverse Saturation current) and "Ro", (Zero-bias Diode resistance). These are the data the set designer requires.

I start off with the realization that when one orders diodes, it is by no means certain what one will get. This seems especially true for the supposedly ubiquitous 1N34A. Unless you see the part number actually on the diode, you probably need to test it to know what it really is. So, lets take a look!

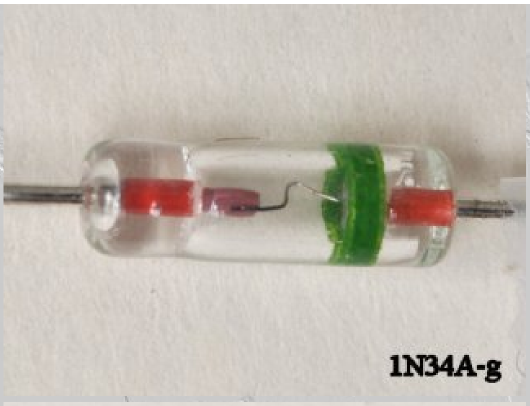
Germanium Diodes



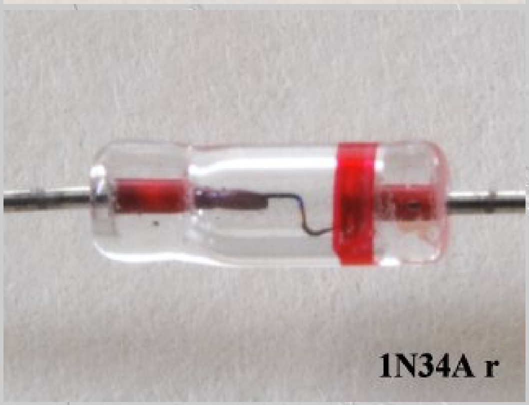
1N34A series



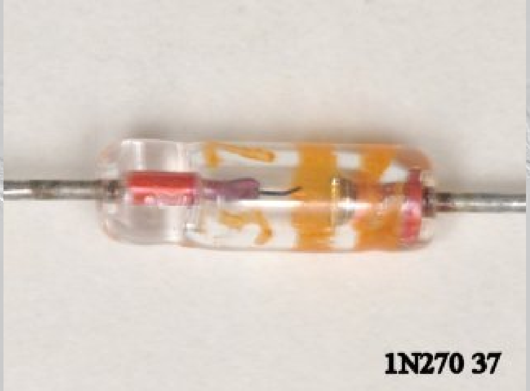
1N34A



1N34A-g



1N34A r



1N270 37

TESLA
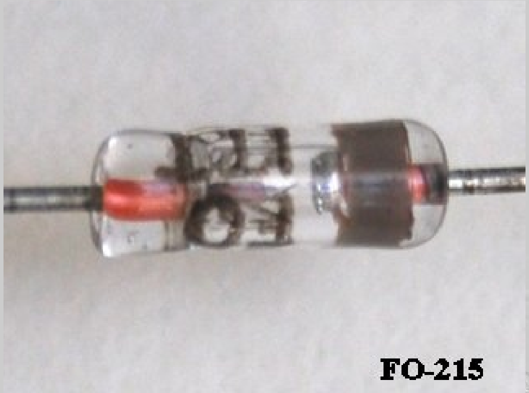
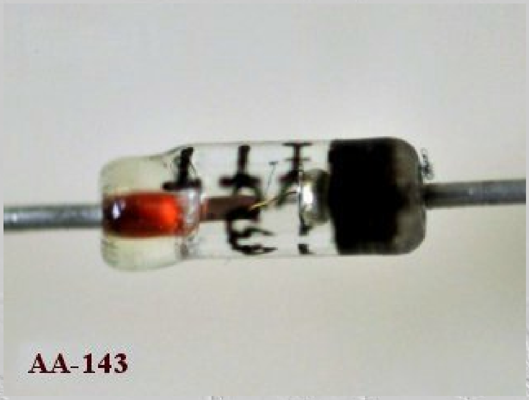
OA5
OA5

ITT Diodes, Something special here.





One oddball Ge diode, not sure what it is for..

Here we see a set of Germanium diodes and photos of the diodes under test. Immediately you should notice two sets of curves, what I call the "1N34A" set and the "1N270-277" set. In this analysis, the second set appears clearly superior in sensitivity and deservedly so. In the photos it is clear that one bunch of diodes I purchased as 1N34A were in fact better 1N277, the black band and thin gold contact wire as well as common curve unite these. "True" 1N34A's have a more robust contact wire. I also purchased a 1N270 and received pretty orange diodes with the number "37" stamped on it, a fairly robust contact wire and a curve that most closely resembles a 1N34A, go figure. Mercifully, I DID manage to get some bona-fide 1N34A's with the part number on the diode, as well as a single bona-fide ITT 1N270 diode with the part number. These are my base for comparison.
In addition to the standard Germanium Diodes tested above, I also have latched my hands on a few "other" germanium diodes for the fun of testing. These include two vintage Russian types, a D9E (in the 270 class) and a D-18 (transitional between 270 and 1N34A). Additionally, I acquired a few FUZZ diodes popular, I suspect, with the guitar gadget crowd. These are larger packages in metal cases so I cannot see how the internal contact is made other that they are stated to be gold bonded point contact type. Clearly these are highly sensitive diodes in my 270 class, the OA5 looking best of the lot. Interestingly, I recently purchased from good Mr. Peebles a few of his "Holy Grail" ITT FO-215 diodes. My measured characteristic for one of these is a dead lay down on the gold-bonded OA5. From the photos, these are in different packaging with the FO-215 in a traditional glass casing. What makes the FO-215 so great is the fact that its resistance Rd is an interesting 150k ohm or so which matches very well with typical moderate Q tank circuits. Interestingly, I find that an old Russian D18 diode has very similar characteristics to the FO-215 and so must also be placed into the "Holy Grail" class of germanium diode. Take your pick!

Spreadsheet for calculation of Germanium diode n and Is (modified from Mike Tuggle's spreadsheet)

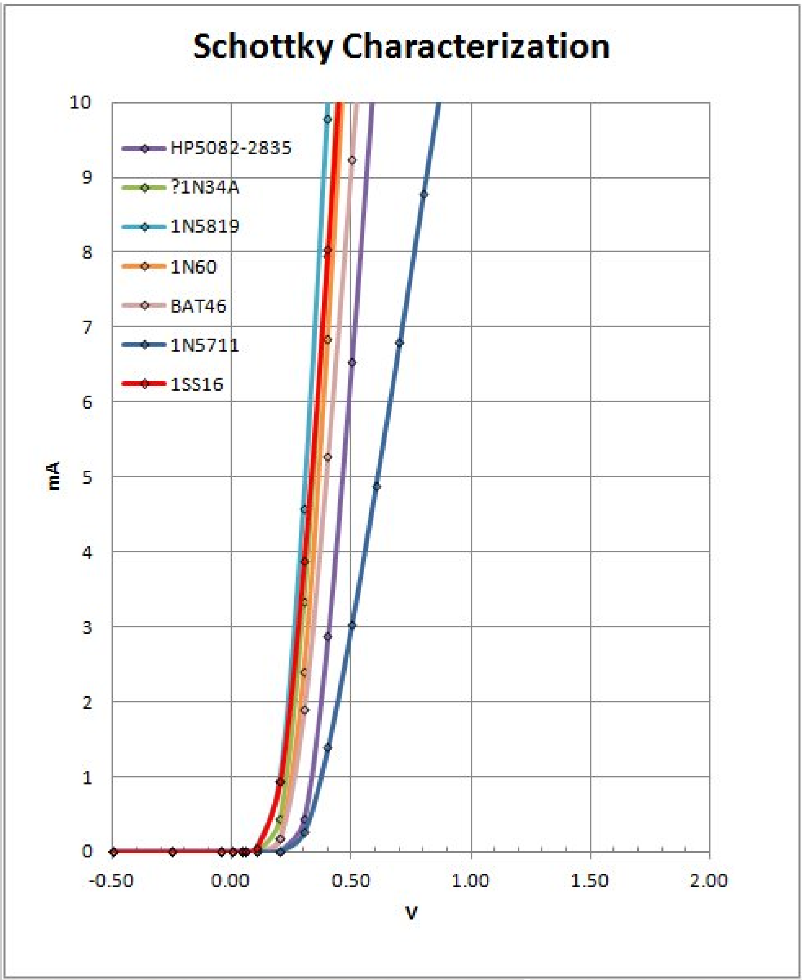
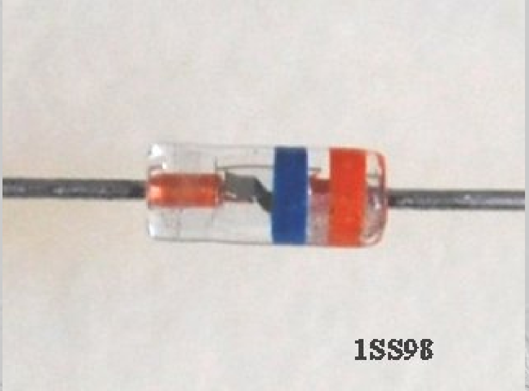
The above spreadsheet is based on measurements of the diodes shown above. For the determination of Is and n, I chose at random two examples from my collection of various diodes, (all germanium in this case) and measured via a modified version of the methodology outlined by Ben Tongue and Mike Tuggle. For this work I have chosen to set Id2 about 0.5uA and Id1 about 1.0uA and then read the needed voltage. This is the inverse of the normal method but the justification is that for any diode regardless of forward voltage drop the measurement is made at the same part of the LOG I vs V characteristic. This allows comparison between all diodes. I have included the actual room temperature in the calculations in order to eliminate this variable as a source of doubt or error. All the measured parameters as well as the determined results are presented in order to facilitate repeatability.

A final note on the plots above. You will have noticed that I sub-divide germanium diodes into a "1N34A" class and a "1N270-277" class. This is a result of looking at their I / V characteristics on a plot of 1 - 2V DC versus 0 - 10mA scale. At such a scale the slope of the characteristic for the 1N270 class remains much steeper than that for 1N34 type diodes. As this is not seen as a distinguishing feature at the small-signal scales looked at here, I judge the chief difference between the two types lies in the diode series resistance Rs. This impacts strong-signals but is of no concern for small-signal DX work. Just so you know.

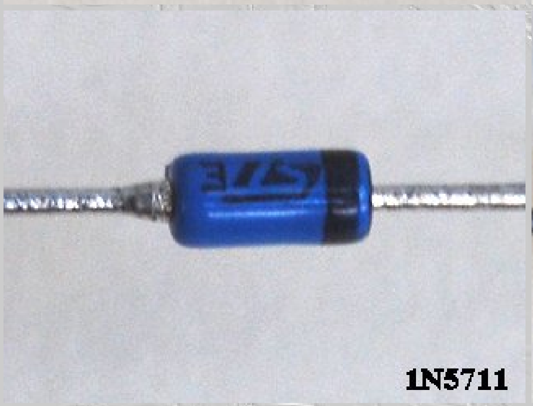
Schottky Diodes



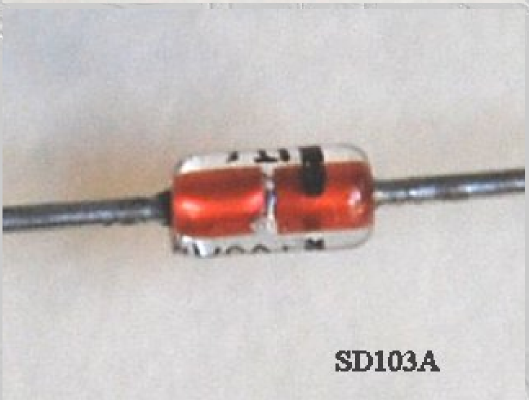
HP5082-2835



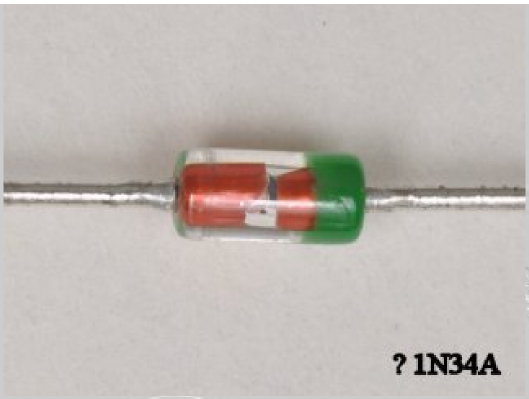
1SS98



1N5711



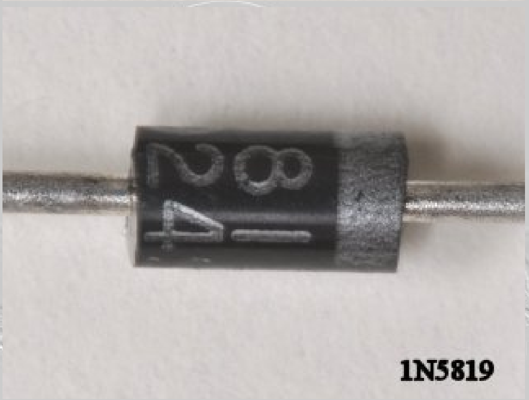
SD103A



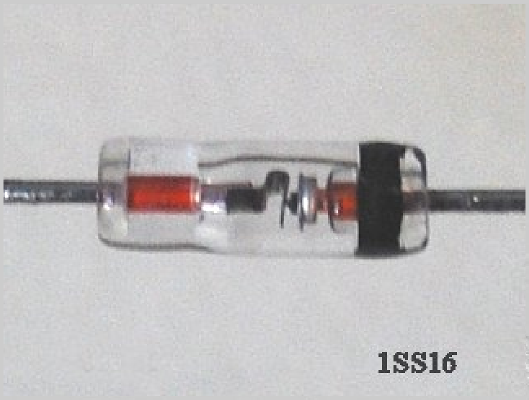
? 1N34A

1N60

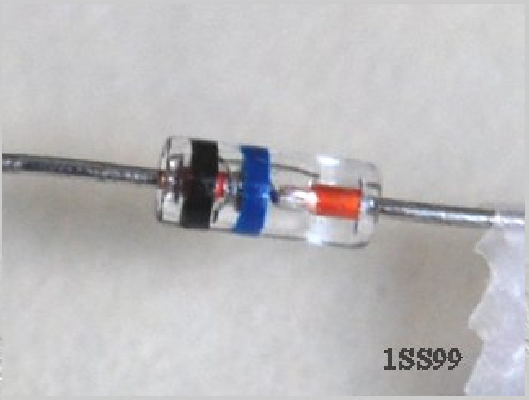
BAT46



1N5819



1SS16



1SS99

Schottky diodes are very sensitive diodes that work excellently in crystal radios. Their construction and theory are different and I confess to not fully understanding these components. Still, from the characteristic curves, they are excellent! Again, note that you don't always get what you bargain for. Here I found what was supposed to be 1N34A's to be some sort of Schottky of unknown pedigree. The 1N5819, while having the lowest forward voltage drop, has a rather very high Junction Capacitance and will not perform well. Posts on the RaidoBoard Crystal Radio Forum however highly recommend the 1N5711 for crystal sets although the characteristic curve doesn't look that fabulous. Many web pages out there on Shottky diodes, I recommend you do your homework. Of all the schottky's, I note that Ben Tongue recommends most highly the HP5083-2835. The high resistance Ro makes them useful for DX sets with very very high Q tanks. Even so the diodes need to be paralleled with up to 4 or 5 diodes to match correctly the Rd with the tank Rp. I have found these somewhat hard to find and expensive, especially when one requires using several in parallel. I recently measured a few 1SS98 diodes and I discover them to have characteristics extremely similar to the HP and I feel they deserve more attention. Sadly, on ebay they seem to be just as difficult to find and expensive. No free ride!

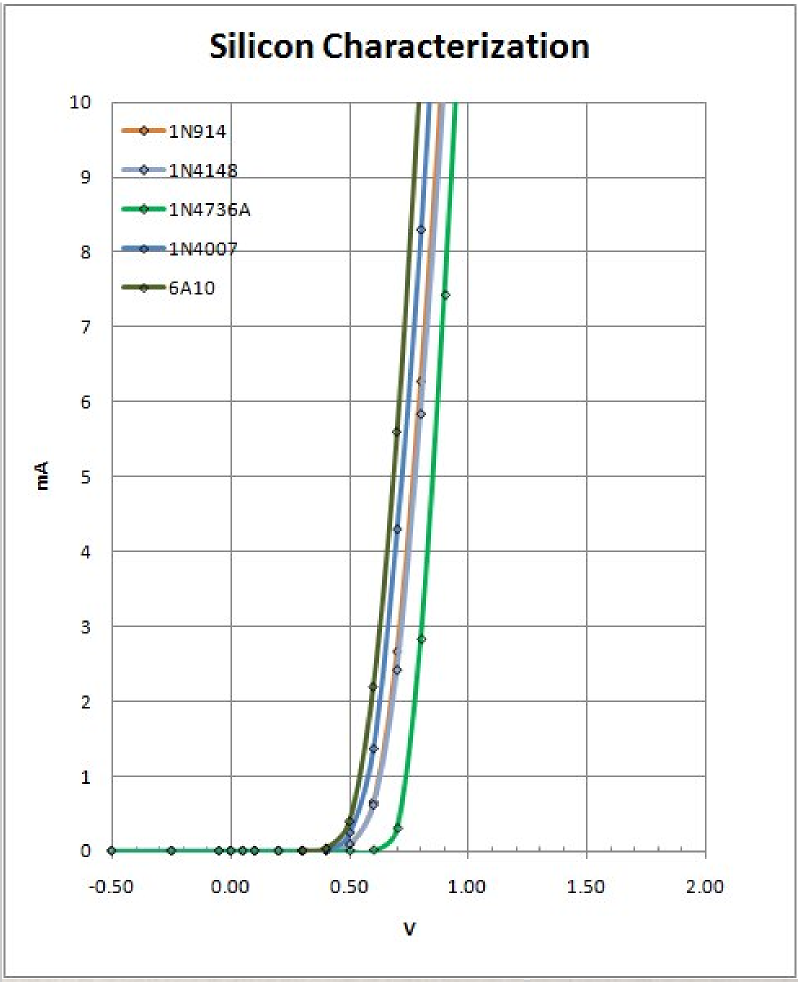
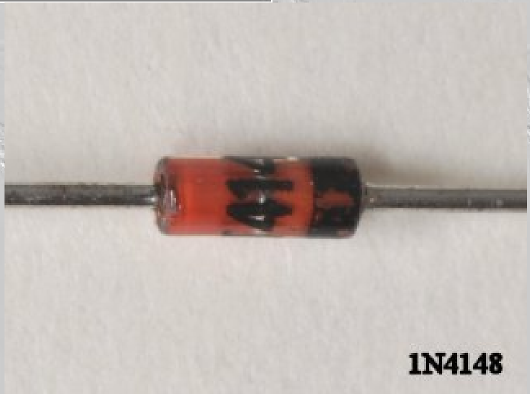
The above spreadsheet is based on measurements of the diodes shown above. For the determination of Is and n, I chose at random two examples from my collection of various diodes, (all schottky in this case) and measured via a modified version of the methodology outlined by Ben Tongue and Mike Tuggle. For this work I have chosen to set Id2 about 0.5uA and Id1 about 1.0uA and then read the needed voltage. This is the inverse of the normal method but the justification is that for any diode regardless of forward voltage drop the measurement is made at the same part of the LOG I vs V characteristic. This allows comparison between all diodes. I have included the actual room temperature in the calculations in order to eliminate this variable as a source of doubt or error. All the measured parameters as well as the determined results are presented in order to facilitate repeatability.

Note in the above data that both the BAT-46 and the 1N60 diodes appear to have excellent properties for crystal radio work. In fact they have very similar parameters overall. Looking at the photos you should also note that the two types of diode look suspiciously exactly alike. The BAT 46 has it correct markings but the 1N60 is unmarked. You never know what you get!

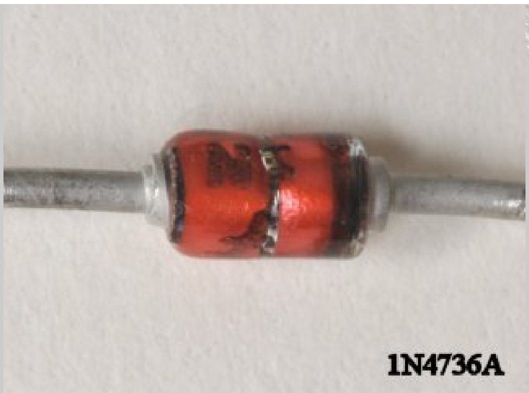
Silicon Diodes



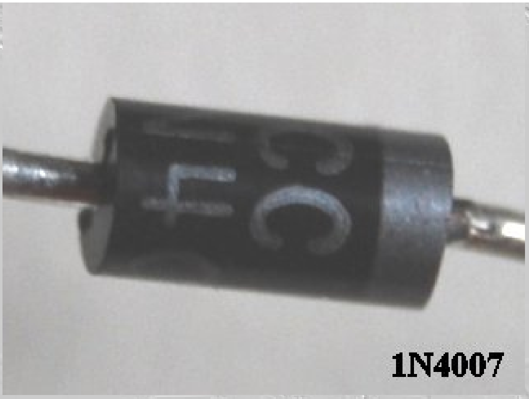
1N914



1N4148



1N4736A



1N4007

6A10

Silicon diodes have good characteristics, but an unacceptably high forward voltage drop making them a very poor choice for crystal radio unless used with bias. The 1N4736A is a Zenner diode.

As long as I am measuring various and sundry diodes, I figure I ought to include that most ubiquitous of modern diode, the LED. Found everywhere, these diodes are rapidly becoming the low-energy light source of choice for many lighting applications. I have read occasionally of someone asking whether these ought to be useful for radio applications as well. To this question the answer is generally a resounding "No!". The turn-on voltage is waaay above any reasonable value expected to be delivered by an antenna to a crystal set. Still, this simple answer avoids the actual question, what in fact does the characteristic curve of a LED really look like? Where is the turn-on voltage with respect to the published junction voltage, (assuming you can find that).

To provide just such a look I visited my local electronics store and bought a small handful of LED's, most with the junction voltage listed and took them home to measure. Typical LED junction voltages seem to range from about 1.8v to 2.1v or more. The turn-on voltages look closer to 1.6v-1.7v. Anyone used to working with Carborundum crystals or silicon diodes will be used to biasing their rectifier to get good sensitivity. These LED's once on have a very sharp rise and with a proper bias should work quite well as detector diodes. As a bonus you will get a sweet glow as well. OK, not as cool as the glow of a vacuum diode, but certainly more sensitive!

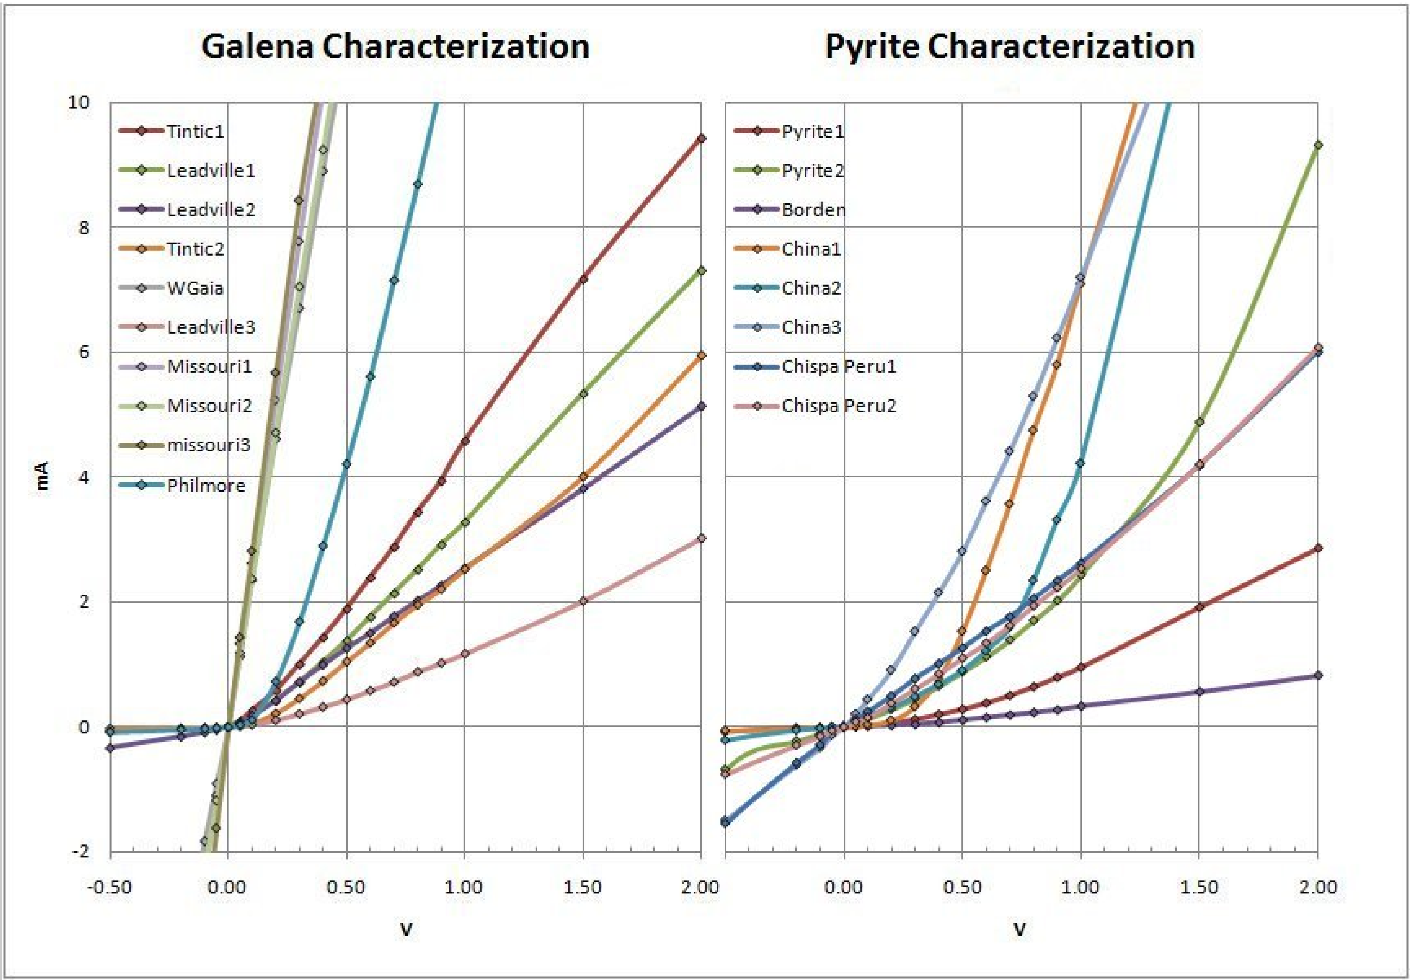
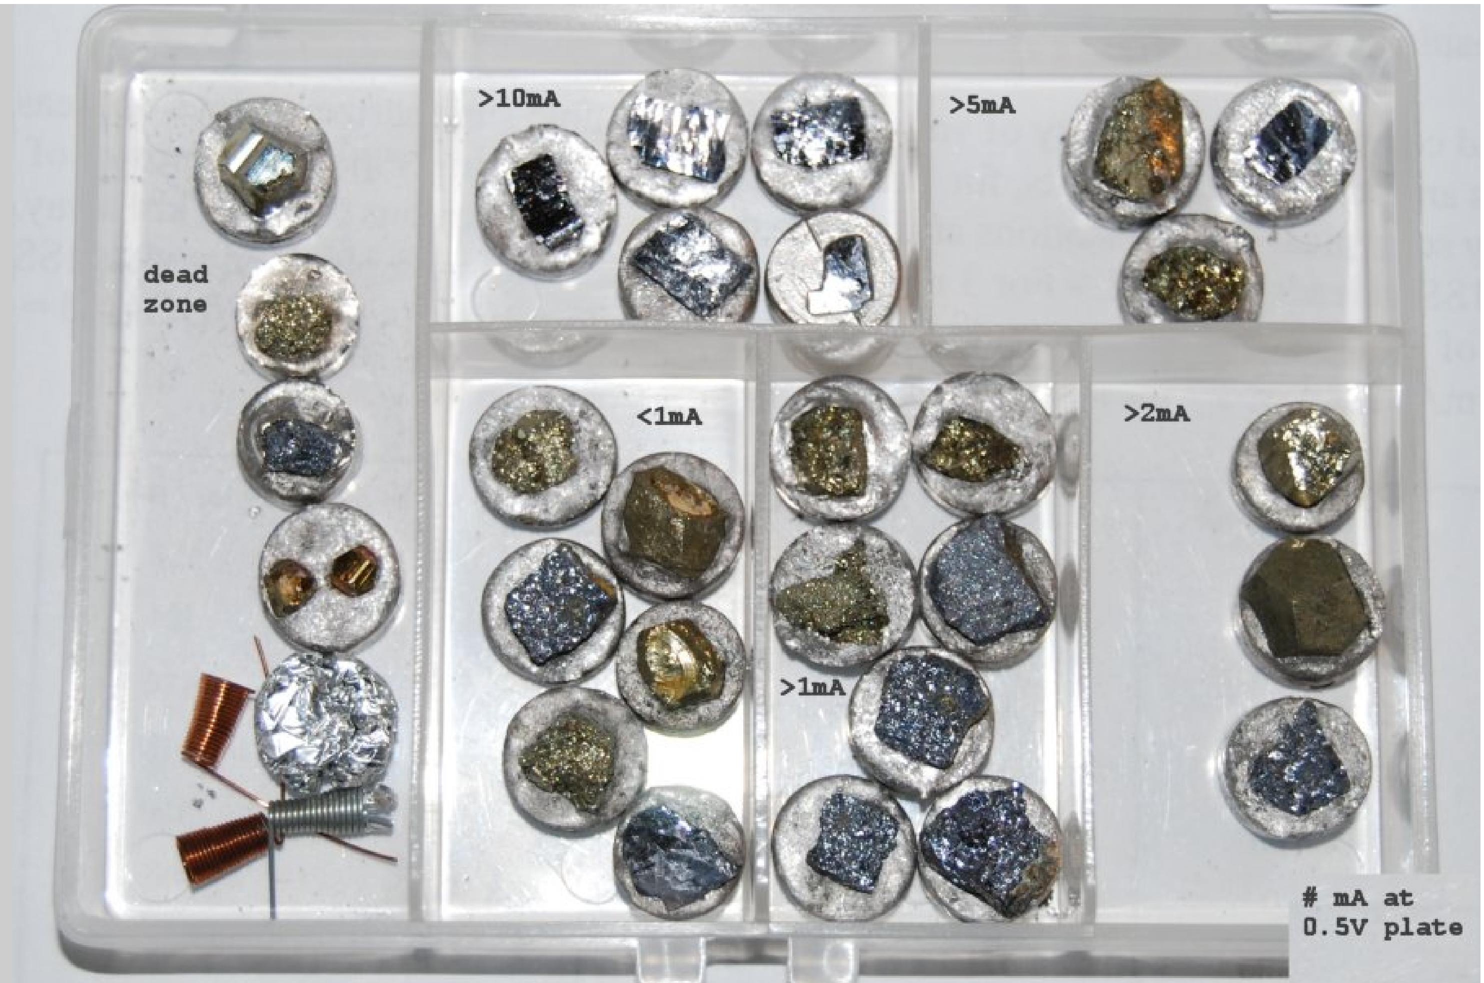
Crystal Galena and Pyrite Diodes



The above curves demonstrate the wide variation in properties and qualities that can be found in natural crystals of galena or pyrite, the two most common and best quality natural stones. In each crystal test I first poked around the crystal for some time to 1) determine a typical sensitivity for the crystal in question and 2) to locate the best hot spot with which to test. This turns out to be a non-trivial exercise on the diode test setup. In a crystal radio one need only listen for the loudest spot. With the test setup one needs test both the forward and reverse current in order to determine if the whisker is on a hot spot or not. Very tedious work! (In retrospect, if I were starting over making a test jig, I would definitely add a DPDT switch to readily change between forward and reverse current measurements. I'd probably toss in a rheostat for fine adjustments as well).

For many crystals there are limited number of possible hot spots, but these may be hot indeed. For most of my "Steel Galena" samples (Tintic Utah, or Leadville Colorado) there are numerous hot spots under virtually every place I touch the probe, but in general the sensitivity is good to so so. These crystals are very kind to work with in terms of finding spots and avoiding frustration. Mirror galena on the other hand may have quality hot spots, but any hot spots at all are rare and frustratingly difficult to locate. Here my Philmore detector crystal shines with an almost ideal "Galena" response. To chase down this rabbit I purchased some lovely mirror galena from Sweetwater Missouri. I broke off a few appropriate-size chunks to pot in woods metal and test. At first I was very excited with the high currents I was seeing at moderate voltages. Figured I had struck gold. When these crystals failed miserably to rectify anything in my radios, I re-measured things in both forward and reverse directions. These crystals obey Ohm's law and act like typical resistors, not suitable for radio work at all.

For my pyrite crystals the work has been especially tedious and frustrating. With one of the crystals one "hot spot" alternated, entirely on its own, between hot and bad while I was making the measurements. I would start over and over, sometimes getting interesting readings then suddenly it would drop to low values and I'd start over, back and forth. I present this data as best as I have measured, and I don't intend to go back! You see at least one of the crystals, my "China 1", (from a lead/silver mine in Hunan) gave a sweet classic-looking curve. More to the point, "ideal" curves for natural minerals are difficult to come by. Most crystals you use will be less than ideal. The good news is that, while listening to your set, poking about for a good spot is far easier than what I have gone through to produce these curves. Your ear will take care of you!



In the photo I indicate groupings based on an easy measure of performance. I note the current in milliamps for each set where the plate voltage is set at 0.5V. The greater the current the better are your chances to get a sensitive crystal, assuming Ohm's Law is not followed! Crystals in the "dead zone" on the left will have their woods metal re-melted for new detector crystals and the bad ones tossed, its tough love for crystals. I find that easily half the potted crystals I make are tossed this way, and only a few can be considered superlative.

My measurements and discussion on vacuum diodes has moved to my section "Diodes III" under the Lab Menu.

Global DX'ter

Back to Radio..

Finally, a shortwave set comes off the design bureau and out into the world. This is a type of set I have been planning and pondering on for some time. With many crystal radio design possibilites this will certainly not be the only SW set I plan, but it is my first effort, my chance to "do it" on shortwave. For a first effort I settled on a fairly simple design, a single-tuned rig with some degree of control, but not overly much. I took as my base a design by Rainer Steinfuehr on his Crystal Reciever World site. This design features a high Q spider coil with two taps, and adjustable capacitance on both the antenna and tuning circuits. It made a rather lovely small set indeed.

The specifics of the design were entirely my own and were based on the frequency range I wished to target and the specifications of the materials I had available for the project. In partictular, I had available small good-quality 10 - 115 pF variable caps for which my clever elder brother had lathed lovely 1/4 inch shaft extenders for use with standard tuning knobs. My target spectrum was about 5 to 18 MHZ as that is where the dominant international BC action takes place. With luck that would also allow receiving WWV at 10 and 15MHz as well. Digging into the design spreadsheets, it seemed an inductor with 7 to 9 mH would best deliver the goods. I made a spider form from a circlar cut of 1/8 inch Delrin plastic and wound 11 turns of 18awg magnet wire, carefully soldering taps at 3 turns and 8 turns from the ground (center) of the coil. I ended with 9 turns on the final set with testing giving me a 7.6 mH coil. The final schematic presented below.

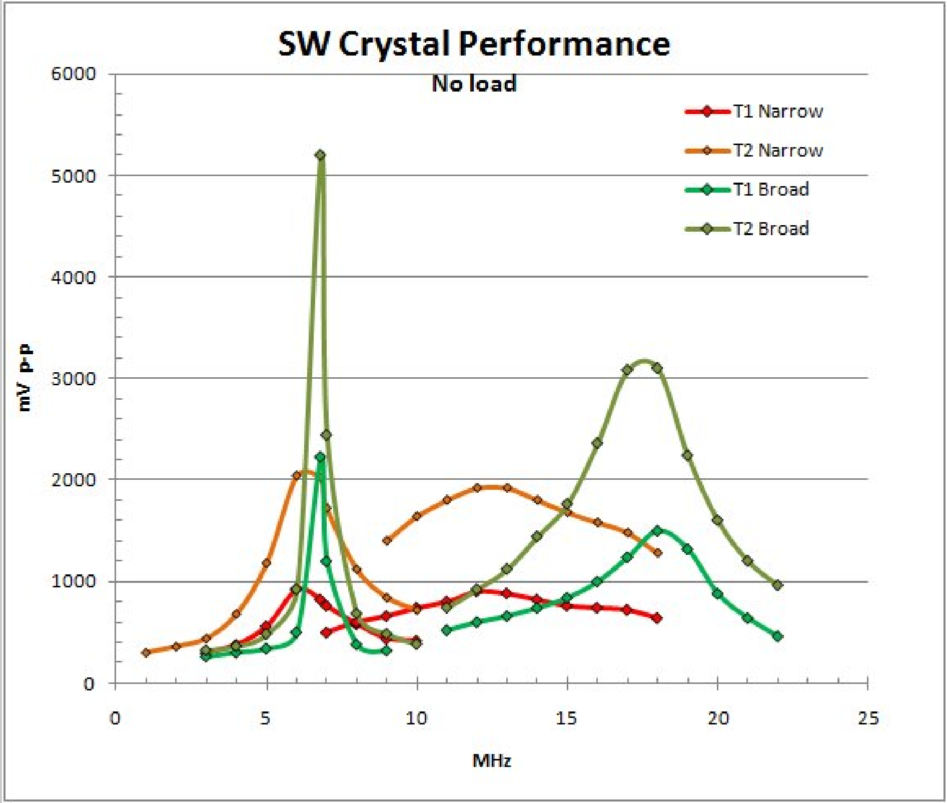
Initial testing on the set was dismal. NO RECEPTION. There followed many hours of double checking all wireing, solder joints, fidelity to the schematic, etc. Everything checked out, no good. Time to seek professional help, which happily corresponded to my annual visit home. There my radio engineer brother took the radio and gave it his close attention, puzzled over it as had I, and concluded a defective part somewhere. This he soon found in the tuning capacitor which had had a connection slip off its set point. This easily corrected, the radio seemed ready for testing. Unfortunately he did not have an antenna handy (he works in uhf+ research stuff) so all I could do was hook the set to a signal generator and test its performance, summarized below.



The plot above charts the received signal strength (p-p mV) versus input frequency for the four possible switch configurations (Detector on tap 1 or 2, Antenna on selective [top of coil] or broad [on tap t1]. These four conditions were tested with the tuning cap fully meshed (low frequency) and fully open (high frequency) to give an idea of the actual tuning range as compared to the calculated range. All measurements were made with no load on the output, and the antenna trim cap in the full meshed position. Other conditions not shown were also tested.

The results indicate that placing the antenna low on the coil, on the T1 position gives the best sensitivity and selectivity in tuning. The detector, a 1N277 germanium diode placed high on the coil at T2 also gives dramatic increase in sensitivity. What I found then, was a farily sensitive but, to be truthful, woefully un-selective set tuning from 6 to about 17-18 MHz. Still, not bad for a single-tuned shortwave rig.

Final thoughts. Upon returning to my home base, I quickly hooked the set to my longwire to make first impressions of actual reception. In midday I was able to pick up a spanish language format broadcast and two english language religous format stations and a brief encounter with WWV. At night the bands are flooded with competing stations, success! Note that all this with my handy dandy Radio Shack mini-amplifier. When I connected a crystal earphone and used my poor hearing, there was nothing as expected. One pity is the ongoing presence, even on this set, of KGOW 1.65MHz forever audible in the background. I consider the set a success as I was not expecting selectivity in a single-tuned rig. Still, with the bands dominated by religous and spanish broadcasts, I cant say it differs much from the local Houston AM fare. Oh well...

Sleeper #1

Back to Radio..

OK, this is a bit of a cheap shot for a radio, but.. it IS a radio!

It is always interesting to get down to bare essentials, to do the absolute minimum and still get a working instrument. It is not for nothing that MB Sleeper included a circuit diagram for this hookup, it is a functionning radio. This circuit is essentially a detector of radio broadcast energy. It has no tuneing functionality. Resonance is extremely broad although weakly peaking as determined by the impedence and capacitance of the antenna itself. In part my idea is to see if it is possible to determine this peak region.
I present the set photo with a 1N5819 Schottky diode but it works well with virtually any diode, only the sensitivity changes. I even tried a Zenner diode but had to attach the Radio Shack mini-amp and crank it up. Still, it worked ok. So, more to come..

As shown, the radio passes most loudly a local powerhouse spanish format station. It is quite sensitive as one can imagine. Listening closely and you can certainly hear the other stations on the broadcast band competing for attention. My question now, do I make a breadboard extravaganza of this set? On va voir...

DIODE SHUNT PARALLEL ACROSS PHONES
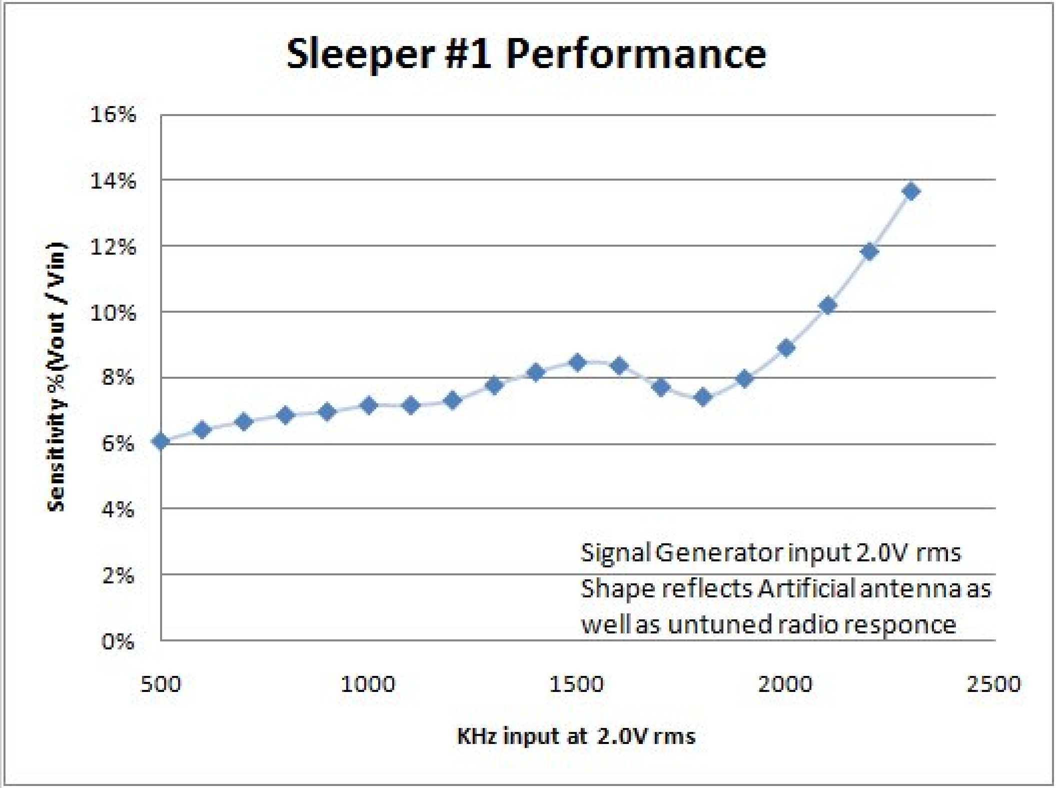
IN SERIES WITH PHONES, LOWER SENSITIVITY.

The hookup in its parallel and series configuragions. In either case I really cannot hear any signal with just a headphone or crystal earplug. With amplification I can get good signal strength with the parallel hookup giving slightly more sensitivity than the series hookup.



Hooking parallel configuration to my signal generator can give an idea of the performance of the radio across the spectrum. I measured the mV output in 100 KHz increments from 500 to 2300 KHz. Across the broadcast band the set has faitly flat responce with a slight tendancy to resonance about 1500 KHz and then increasing sensitivity from 1900 KHz on up. Keep in mind that the set is hooked to a dummy antenna rather than my actual long wire. Still this gives an idea of the overall untuned nature of the circuit.

When I hook in a series configuraiton I am unable to get a measurement, only 0V DC output. I am working on why this may be the case. Drives me nuts.

Wavetrap, a useful gadget

[Back to Radio..](#)

This little gadget is most handy for crunching those local behemoths that always seem to be directing their strongest signals right in your direction. My wave trap is a bit of a combination of 1) Osterhoudt's QRM coil, 2) a design I found online on Owen Pool's excellent web site, and 3) a bit of my own seeing as how I had some, but not all of the ingredients needed from both traps. That is, I used what I found in the junk box.

The trap is formed on a stiff cardboard paper core with 1 1/4 inch outside diameter. On this I drilled holes for winding the tank coil, 110 turns of #30 awg enameled wire. Both Poole and Osterhoudt recommend #32, but 30 is what I had. Over this I would a coupling coil, 15 turns space wound of #22 awg enameled wire. Tuning of the tank is completed with a 410 pF var cap.

Tuning is sharp and deep, it takes a bit of getting used to, but then, schezzam!!!.. problem station gone! I luv it.

[57] ABSTRACT

The present invention relates to a method and apparatus for operating an engine having a cylinder and a piston reciprocable therein on compressed gas. The apparatus comprises a source of compressed gas connected to a distributor which distributes the compressed gas to the cylinder. A valve is provided to selectively admit compressed gas to the cylinder when the piston is in an approximately top dead center position. In one embodiment of the present invention the timing of the opening of the valve is advanced such that the compressed gas is admitted to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases. In a further embodiment of the present invention a valve actuator is provided which increases the length of time over which the valve remains open to admit compressed gas to the cylinder as the speed of the engine increases. A still further embodiment of the present invention relates to an apparatus for adapting a conventional internal combustion engine for operation on compressed gas.

METHOD AND APPARATUS FOR OPERATING AN ENGINE ON COMPRESSED GAS

BACKGROUND AND SUMMARY OF THE PRESENT INVENTION

The present invention relates to a method and apparatus for operating an engine using a compressed gas as the motive fluid. More particularly, the present invention relates to a apparatus for adapting a pre-existing internal combustion engine for operation on a compressed gas.

Air pollution is one of the most serious problems facing the world today. One of the major contributors to air pollution is ordinary internal combustion engine which are used in most motor vehicles today. Various devices, including many items mandated by legislation, have been proposed in an attempt to limit the pollutants which an internal combustion engine exhausts to the air. However, most of these devices have met with limited success and are often both prohibitively expensive and complex. A clean alternative to the internal combustion engine is needed to power vehicles and other machinery.

A compressed gas, preferably air, would provide an ideal motive fluid for a engine since it would eliminate the usual pollutants exhausted from an internal combustion engine. An apparatus for converting an internal combustion engine for operation on compressed air is disclosed in U.S. Pat. No. 3,885,387 issued May 27, 1975 to Simington. The Simington patent discloses an apparatus including a source of compressed air and a rotating valve actuator which opens and closes a plurality of mechanical poppet valves. The valves deliver compressed air in timed sequence to the cylinders of an engine through adapters located in the spark plug holes. However, the output speed of an engine of this type is limited by the speed of the mechanical valves and the fact that the length of time over which each of the valves remains open cannot be varied as the speed of the engine increases.

Another apparatus for converting an internal combustion engine for operation on steam or compressed air is disclosed in U.S. Pat. No. 4,102,130 issued July 25, 1978 to Stricklin. The Stricklin patent discloses a device which changes the valve timing of a conventional four stroke engine such that the intake and exhaust valves open once for every revolution of the engine instead of once every other revolution of the engine. A reversing valve is provided which delivers live steam or compressed air to the intake valves and is subsequently reversed to allow the exhaust valves to deliver the expanded steam or air to the atmosphere. A reversing valve of this type however does not provide a reliable apparatus for varying the amount of motive fluid injected into the cylinders when it is desired to increase the speed of the engine. Further, a device of the type disclosed in the Stricklin patent requires the use of multiple reversing valves if the cylinders in a multi-cylinder engine were to be fired sequentially.

Therefore, it is an object of the present invention to provide a reliable method and apparatus for operating an engine or converting an engine for operation with a compressed gas.

A further object of the present invention is to provide a method and apparatus which is effective to deliver a constantly increasing amount of compressed gas to an engine as the speed of the engine increases.

A still further object of the present invention is to provide a method and apparatus which will operate an engine using compressed gas at a speed sufficient to drive a conventional automobile at highway speeds.

It is still a further object of the present invention to provide a method and apparatus which is readily adaptable to a standard internal combustion engine to convert the internal combustion engine for operation with a compressed gas.

Another object of the invention is to provide a method and apparatus which utilizes cool expanded gas, exhausted from a compressed gas engine, to operate an air conditioning unit and/or an oil cooler.

These and other objects are realized by a method and apparatus according to the present invention for operating an engine having at least one cylinder and a reciprricating piston therein using compressed gas as a motive fluid. The apparatus includes a source of compressed gas and a distributor connected with the source of the compressed gas for distributing the compressed gas to the at least one cylinder. A valve is provided for admitting the compressed gas to the cylinder when the piston is in approximately a top dead center position within the cylinder. An exhaust is provided for exhausting the expanded gas from the cylinder as the piston returns to approximately the top dead center position.

In a preferred embodiment of the present invention a device is provided for varying the duration of each engine cycle over which the valve remains open to admit compressed gas to the cylinder dependent upon the speed of the engine. In a further preferred embodiment of the present invention, an apparatus for advancing the timing of the opening of the valve is arranged to admit the compressed gas to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases.

Further features of the present invention include a valve for controlling the amount of compressed gas admitted to the distributor. Also, a portion of the gas which has been expanded in the cylinder and exhausted through the exhaust valve is delivered to a compressor to be recompressed and returned to the source of compressed gas. A gear train is selectively engagable to drive the compressor at different operating speed depending upon the pressure maintained at the source of compressed air and/or the speed of the engine. Still further, a second portion of the exhaust gas is used to cool a lubricating fluid for the engine or to operate an air conditioning unit.

In a preferred embodiment of the present invention, the valve for admitting compressed gas to the cylinder is electrically actuated. The device for varying the duration of each engine cycle over which the intake valve remains open as the speed of the engine increase comprises a rotating element whose effective length increases as the speed of the engine increases such that a first contact on the rotating element is electrically connected to a second contact for a longer period of each engine cycle. The second contact actuates the valve whereby the valve remains in an open position for a longer period of each engine cycle as the speed of the engine increases.

Still further features of the present invention include an adaptor plate for supporting the distributor above an intake manifold of a conventional internal combustion engine after a carburetor has been removed to allow air

to enter the cylinders of the engine through the intake manifold and conventional intake valves. Another adaptor plate is arranged over an exhaust passageway of the internal combustion engine to reduce the cross-sectional area of the exhaust passageway.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of a method and apparatus for operating an engine according to the present invention will be described with reference to the accompanying drawings wherein like members bear like reference numerals and wherein:

FIG. 1 is a schematic representation of an apparatus according to the present invention arranged on an engine;

FIG. 2 is a side view of one embodiment of a valve actuator according to the present invention;

FIG. 3 is a cross-sectional view taken along the line 3—3 in FIG. 2;

FIG. 4 is a cross-sectional view of a second embodiment of a valve actuator according to the present invention;

FIG. 5 is a view taken along the line 5—5 in FIG. 4;

FIG. 6 is a cross-sectional view of a third embodiment of a valve actuator according to the present invention;

FIG. 7 is a view taken along the line 7—7 in FIG. 6;

FIG. 8 is a cross-sectional view of a gearing unit to drive a compressor according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to FIG. 1, an engine block **21** (shown in phantom) having two banks of cylinders with each bank including cylinders **20** having pistons **22** reciprocable therein (only one of which is shown in phantom) in a conventional manner. While the illustrated engine is a V-8 engine, it will be apparent that the present invention is applicable to an engine having any number of pistons and cylinders with the V-8 engine being utilized for illustration purposes only. A compressed gas tank **23** is provided to store a compressed gas at high pressure. It may also be desirable to include a small electric or gas compressor to provide compressed gas to supplement the compressed gas held in the tank **23**. In a preferred embodiment, the compressed gas is air which can be obtained from any suitable source.

A line **25** transports the gas withdrawn from the tank **23** when a conventional shut off valve **27** is open. In addition, a solenoid valve **29** preferably operated by a suitable key operated switch (not shown) for the engine is also arranged in the line **25**. In normal operation, the valve **27** is maintained open at all times with the solenoid valve **29** operating as a selective shut off valve to start and stop the engine **21** of the present invention.

A suitable regulating valve **31** is arranged downstream from the solenoid valve **29** and is connected by a linkage **33** to a throttle linkage **35** which is operator actuated by any suitable apparatus such as a foot pedal (not shown). The line **25** enters an end of a distributor **33** and is connected to an end of a pipe **35** which is closed at the other end. A plurality of holes, which are equal to the number of cylinders in the engine **21**, are provided on either side of the pipe **35** along the length of the pipe **35**.

When the present invention is used to adapt a conventional internal combustion engine for operation on compressed gas, an adaptor plate **36** is provided to support the distributor **33** in spaced relation from the usual intake opening in the intake manifold of the engine after a conventional carburetor has been removed. In this way, air is permitted to enter the internal combustion engine through the usual passageways and to be admitted to the cylinders through suitable intake valves (not shown). The adaptor plate **36** is secured to the engine block **21** and the distributor **33** by any suitable apparatus, e.g., bolts.

Each of the holes in the pipe **35** is connected in fluid-tight manner to a single line **37**. Each line **37** carries the compressed gas to a single cylinder **20**. In a preferred embodiment, each of the lines **37** is $\frac{1}{2}$ inch high pressure plastic tubing attached through suitable connectors to the distributor **33** and the pipe **35**. Each of the lines **37** is connected to a valve **39** which is secured in an opening provided near the top of each of the cylinders **20**. In the case of a conversion of a standard internal combustion engine, the valves **39** can be conveniently screwed into a tapped hole in the cylinder **20** typically provided for a spark plug of the internal combustion engine. In a preferred embodiment, the valves **39** are solenoid actuated valves in order to provide a fast and reliable opening and closing of the valves **39**.

Each of the valves **39** is energized by a valve actuator **41** through one of a plurality of wires **43**. The valve actuator **41** is driven by a shaft of the engine similar to the drive for a conventional distributor of an internal combustion engine. That is, a shaft **55** of the valve actuator **41** is driven in synchronism with the engine **21** at one half the speed of the engine **21**.

A first embodiment of the valve actuator **41** (FIGS. 2 and 3) receives electrical power through a wire **45** which is energized in a suitable manner by a battery, and a coil if necessary (not shown) as is conventional in an internal combustion engine. The wire **45** is attached to a central post **47** by a nut **49**. The post **47** is connected to a conducting plate **51** arranged within a housing **53** for the valve actuator **41**. Within the housing **53**, the shaft **55** has an insulating element **57** secured to an end of the shaft **55** for co-rotation therewith when the shaft **55** is driven by the engine **21**. A first end of a flexible contact **59** is continuously biased against the conducting plate **51** to receive electricity from the battery or another suitable source. A second end of the contact **59** is connected to a conducting sleeve **60** which is in constant contact with a spring biased contact **61** which is arranged within the sleeve **60**. The contact **61** is biased by a spring **63** which urges the contact **61** towards a side wall of the housing **53**.

With reference to FIG. 3, a plurality of contacts **65** are spaced from one another and are arranged around the periphery of the housing **53** at the same level as the spring biased contact **61**. Each contact **65** is electrically connected to a post **67** which extends outside of the housing **53**. The number of contacts **65** is equal to the number of cylinders in the engine **21**. One of the wires **43**, which actuate the valves **39**, is secured to each of the posts **67**.

In operation, as the shaft **55** rotates in synchronism with the engine **21**, the insulating element **57** rotates and electricity is ultimately delivered to successive ones of the contacts **65** and wires **43** through the spring biased contact **61** and the flexible contact **59**. In this way, each of the electrical valves **39** is actuated and opened in the proper timed sequence to admit compressed gas to each of the cylinders **20** to drive the pistons **22** therein on a downward stroke.

The embodiment illustrated in FIGS. 2 and 3 is effective to actuate each of the valves 39 to remain open for a long enough period of time to admit sufficient compressed gas to each of the cylinders 20 of the engine 21 to drive the engine 21. The length of each of the contacts 65 around the periphery of the housing 53 is sufficient to permit the speed of the engine to be increased when desired by the operator by moving the throttle linkage 35 which actuates the linkage 33 to further open the regulating valve 31 to admit more compressed gas from the tank 23 to the distributor 33. However, it has been found that the amount of air admitted by the valves 39 when using the first embodiment of the valve actuator 41 (FIGS. 2 and 3) is substantially more than required to operate the engine 21 at an idling speed. Therefore, it may be desirable to provide a valve actuator 41 which is capable of varying the duration of each engine cycle over which the solenoid valves 39 are actuated, i.e., remain open to admit compressed gas, as the speed of the engine 21 is varied.

A second embodiment of a valve actuator 41 which is capable of varying the duration of each engine cycle over which each of the valves 39 remains open to admit compressed gas to the cylinders 20 dependent upon the speed of the engine 21 will be described with reference to FIGS. 4 and 5 wherein members corresponding to those of FIGS. 2 and 3 bear like reference numerals. The wire 45 from the electrical source is secured to the post 47 by the nut 49. The post 47 has a annular contact ring 69 electrically connected to an end of the post 47 and arranged within the housing 53. The shaft 55 rotates at one half the speed of the engine as in the embodiment of FIGS. 2 and 3.

At an upper end of the shaft 55, a splined section 71 slidably receives an insulating member 73. The splined section 71 of the shaft 55 positively holds the insulating member 73 for co-rotation therewith but permits the insulating member 73 to slide axially along the length of the splined section 71. Near the shaft 55, a conductive sleeve 72 is arranged in a bore 81 in an upper surface of the insulating element 73 generally parallel to the splined section 71. A contact 75, biased towards the annular contact ring 69 by a spring 77, is arranged within the conductive sleeve 72 in contact therewith. The conductive sleeve 72 also contacts a conductor 79 at a base of the bore 81.

The conductor 79 extends to the upper surface of the insulating element 73 near an outer periphery of the insulating element 73 where the conductor 79 is electrically connected to a flexible contact 83. The flexible contact 83 selectively engages a plurality of radial contacts 85 arranged on an upper inside surface of the housing 53. A weak spring 87 arranged around the splined section 71 engages a stop member 89 secured on the shaft 55 and the insulating element 73 to slightly bias the insulating element 73 towards the upper inside surface of the housing 53 to ensure contact between the flexible contact 83 and the upper inside surface of the housing 53. As best seen in FIG. 5, the radial contacts 85 on the upper inside surface of the housing 53 are arranged generally in the form of radial spokes extending from the center of the housing 53 with the number of contacts being equal to the number of cylinders 20 in the engine 21. The number of degrees covered by each of the radial contacts 85 gradually increases as the distance from the center of the upper inside surface of the housing 53 increases.

In operation of the device of FIGS. 4 and 5, as the shaft 55 rotates, electricity flows along a path through the wire 45 down through post 47 to the annular contact member 69 which is in constant contact with the spring biased contact 75. The electrical current passes through the conductive sleeve 72 to the conductor 79 and then to the flexible contact 83. As the flexible contact 83 rotates along with the insulating member 73 and the shaft 55, the tip of the flexible contact 83 successively engages each of the radial contacts 85 on the upper inside of the housing 53. As the speed of the shaft 55 increases, the insulating member 73 and the flexible contact 83 attached thereto move upwardly along the splined section 71 of the shaft 55 due to the radial component of the splines in the direction of rotation under the influence of centrifugal force. As the insulating member 73 moves upwardly, the flexible contact 83 is bent such that the tip of the contact 83 extends further radially outwardly from the center of the housing 53 (as seen in phantom lines in FIG. 4). In other words, the effective length of the flexible contact 83 increases as the speed of the engine 21 increases.

As the flexible contact 83 is bent and the tip of the contact 83 moves outwardly, the tip remains in contact with each of the radial contacts 85 for a longer period of each engine cycle due to the increased angular width of the radial contacts with increasing distance from the center of the housing 53. In this way, the length of time over which each of the valves 39 remains open is increased as the speed of the engine is increased. Thus, a larger quantity of compressed gas or air is injected into the cylinders as the speed increases. Conversely, as the speed decreases and the insulating member 73 moves downwardly along the splined section 71, a minimum quantity of air is injected into the cylinder due to the shorter length of the individual radial contact 85 which is in contact with the flexible contact 83. In this way, the amount of compressed gas that is used during idling of the engine 21 is at a minimum whereas the amount of compressed gas which is required to increase the speed of the engine 21 to a level suitable to drive a vehicle on a highway is readily available.

With reference to FIGS. 6 and 7, a third embodiment of a valve actuator 41 according to the present invention includes an arcuate insulating element 91 having a first end pivotally secured by any suitable device such as screw 92 to the shaft 55 for co-rotation with the shaft 55. The screw 92 is screwed into a tapped hole in the insulating element 91 such that a tab 94 at an end of the screw 92 engages a groove 96 provided in the shaft 55. In this way, the insulating element 91 positively rotates with the shaft 55. However, as the shaft 55 rotates faster, a second end 98 of the insulating element 91 is permitted to pivot outwardly under the influence of centrifugal force because of the groove 96 provided in the shaft 55. A spring 93 connected between the second end 98 of the element 91 and the shaft 55 urges the second end of the element 91 towards the center of the housing 53.

A contact 99 similar to the contact 59 (FIG. 2) is arranged such that one end of the contact 99 is in constant contact with the conducting plate 51 located centrally within the housing 53. The other end of the contact 99 engages a conductive sleeve 101 arranged in bore 102. A contact element 95 is arranged in the conductive sleeve 101 in constant contact with the sleeve 101. The bore 102 is arranged generally parallel to the shaft 55 near the second end of the arcuate insulating

element **91**. The contact **95** is biased by a spring **97** towards the upper inside surface of the housing **53** for selective contact with each of the plurality of radial contacts **85** which increase in arc length towards the outer peripheral surface of the housing **53** (FIG. **6**).

In operation of the device of FIGS. **6** and **7**, as the shaft **55** rotates the arcuate insulating element **91** rotates with the shaft **55** and the second end **98** of the insulating element **91** tends to pivot about the shaft **55** due to centrifugal force. Thus, as the effective length of the contact **95** increases, i.e., as the arcuate insulating element **91** pivots further outwardly, the number of degrees of rotation over which the contact **95** is in contact with each of the radial contacts **85** on the upper inside surface of the housing **53** increases thereby permitting each of the valves **39** to remain open for a longer period of each engine cycle to admit more compressed gas to the respective cylinder **20** to further increase the speed of the engine **21**.

With reference to FIG. **1**, a mechanical advance linkage **104** which is connected to the throttle linkage **35**, advances the initiation of the opening of each valve **39** such that compressed gas is injected into the respective cylinder further before the piston **22** in the respective cylinder **20** reaches a top dead center position as the speed of the engine is increased by moving the throttle linkage **35**. The advance linkage **104** is similar to a conventional standard mechanical advance employed on an internal combustion engine. In other words, the linkage **104** varies the relationship between the angular positions of a point on the shaft **55** and a point on the housing **53** containing the contacts. Alternatively, a conventional vacuum advance could also be employed. By advancing the timing of the opening of the valves **39**, the speed of the engine can more easily be increased.

The operation of the engine cycle according to the present invention will now be described. The compressed gas injected into each cylinder of the engine **21** drives the respective piston **22** downward to drive a conventional crankshaft (not shown). The movement of the piston downwardly causes the compressed gas to expand rapidly and cool. As the piston **22** begins to move upwardly in the cylinder **20** a suitable exhaust valve (not shown) arranged to close an exhaust passageway is opened by any suitable apparatus. The expanded gas is then expelled through the exhaust passageway. As the piston **22** again begins to move downwardly a suitable intake valve opens to admit ambient air to the cylinder. The intake valve closes and the ambient air is compressed on the subsequent upward movement of the piston until the piston reaches approximately the top dead center position at which time the compressed gas is again injected into the cylinder **20** to drive the piston **22** downward and the cycle begins anew.

In the case of adapting a conventional internal combustion engine for operation on compressed gas, a plurality of plates **103** are preferably arranged over an end of the exhaust passageways in order to reduce the outlet size of the exhaust passageways of the conventional internal combustion engine. In the illustrated embodiment, a single plate having an opening in the center is bolted to the outside exhaust passageway on each bank of the V-8 engine while another single plate having two openings therein is arranged with one opening over each of the interior exhaust passageways on each bank of the V-8 engine. A line **105** is suitably attached to each of the adaptor places to carry the exhaust to an appropriate location. In a preferred embodiment, the exhaust lines **105** are 1½" plastic tubing.

In a preferred embodiment, the exhaust lines **105** of one bank of the V-8 engine are collected in a line **107** and fed to an inlet of a compressor **109**. The pressure of the exhaust gas emmanating from the engine **21** according to the present invention is approximately 25 p.s.i. In this way, the compressor **109** does not have to pull the exhaust into the compressor since the gas exhausted from the engine **21** is at a positive pressure. The positive pressure of the incoming fluid increases the efficiency and reduces wear on the compressor **109**. The exhaust gas is compressed in the compressor **109** and returned through a line **111** and a check valve **113** to the compressed gas storage tank **23**. The check valve **113** prevents the flow of compressed gas stored in the tank **23** back towards the compressor **109**.

A suitable pressure sensor **115** is arranged at an upper end of the tank **23** and sends a signal along a line **117** when the pressure exceeds a predetermined level and when the pressure drops below a predetermined level. The line **117** controls an electrically actuated clutch **119** disposed at a front end of the compressor **109**. The clutch **119** is operative to engage and disengage the compressor **109** from a drive pulley **121**. Also, the signal carried by the line **117** actuates a suitable valve **123** arranged on a compressor housing **125** to exhaust the air entering the compressor housing **125** from the line **107** when the clutch **119** has disengaged the compressor **109** from the drive pully **121**.

In a preferred embodiment, when the pressure is the tank **23** reaches approximately 600 p.s.i., the clutch **119** is disengaged and the compressor **109** is deactivated and the valve **123** is opened to exhaust the expanded gas delivered to the compressor **109** from the line **107** to the atmosphere. When the pressure within the tank **23** drops below approximately 500 p.s.i., the sensor **115** sends a signal to engage the clutch **119** and close the valve **123**, thereby operating the compressor **109** for supplying the tank **23** with compressed gas.

The pulley **121** which drives the compressor **109** through the clutch **119** is driven by a belt **127** which is driven by a pulley **129** which operates through a gear box **131**. With reference to FIGS. **1** and **8**, a second pulley **133** on the gear box is driven by a belt **135** from a pulley **137** arranged on a drive shaft **139** of the engine **21**. The pulley **137** drives a splined shaft **140** which has a first gear **141** and a second larger gear **143** arranged thereon for rotation with the splined shaft **140**. The splined shaft **140** permits axial movement of the gears **141** and **143** along the shaft **140**.

In normal operation (as seen in FIG. **8**), the first gear **141** engages a third gear **145** arranged on a shaft **147** which drives the pulley **129**. The shafts **140** and **147** are arranged in suitable bearings **149** arranged at each end thereof. When the speed of the engine **21** drops below a predetermined level, a suitable sensor **151** responsive to the speed of the drive shaft **139** of the engine **21** generates a signal which is transmitted through a line **153** to a solenoid actuator **155** arranged within the gear box **131**. The solenoid actuator **155** moves the first and second gears **141**, **143** axially along the splined shaft **140** to the right as seen in FIG. **8** such that the second, larger gear **143** engages a fourth smaller gear **157** which is arranged on the shaft **147**. The ratio of the second gear **143** to the fourth gear **157** is preferably approximately 3 to 1.

In this way, when the speed of the engine **21** drops below the predetermined level as sensed by the sensor **151** (which predetermined level is insufficient to drive the compressor **109** at a speed sufficient to generate the 500-600 pounds of pressure which is preferably in the tank **23**), the solenoid actuator **155** is energized to slide the gears **143**, **141** axially along the splined shaft **140** so that the second, larger gear **143** engages the fourth, smaller gear **157** to drive the pulley **129** and hence the compressor **109** at a higher rate of speed to generate the desired pressure. When the speed of the engine increases above the predetermined level, in a preferred embodiment approximately 1500 rpm, the solenoid actuator **155** is deactivated by the sensor **151** thereby moving the gears **143** and **141** to the left as seen in FIG. **8** such that the first gear **141** re-engages with the third gear **145** to effectuate a 1 to 1 ratio between the output shaft **139** of the engine **21** and the pulley **129**.

The other bank of the V-8 engine has its exhaust ports arranged with adapter plates **103** similar to those on the first bank. However, the exhaust from this bank of the engine **21** is not collected and circulated through the compressor **109**. In a preferred embodiment, a portion of the exhaust is collected in a line **159** and fed to an enlarged chamber **161**. A second fluid is fed through a line **163** into the chamber **161** to be cooled by the cool exhaust emmanating from the engine **21** in the line **159**. The second fluid in the line **163** may be either transmission fluid contained in a transmission associated with the engine **21** or a portion of the oil used to lubricate the engine **21**. A second portion of the exhaust from the second bank of the V-8 engine is removed from the line **159** in a line **165** and used as a working fluid in an air conditioning system or for any other suitable use.

It should be noted that the particular arrangement utilized for collecting and distributing the gas exhausted from the engine **21** would be determined by the use for which the engine is employed. In other words, it may be advantageous to rearrange the exhaust tubing such that a larger or smaller percentage of the exhaust is routed through the compressor **109**. It should also be noted that since the exhaust lines **105** are plastic tubing, a rearrangement of the lines for a different purpose is both simple and inexpensive.

In operation of the engine of the present invention, the engine **21** is started by energizing the solenoid valve **29** and any suitable starting device (not shown), e.g., a conventional electric starter as used on an internal combustion engine. Compressed gas from the full tank **23** flows through the line **25** and a variable amount of the compressed gas is admitted to the distributor **33** by controlling the regulator valve **31** through the linkage **33** and the operator actuated throttle linkage **35**. The compressed gas is distributed to each of the lines **37** which lead to the individual cylinders **20**. The compressed gas is admitted to each of the cylinders **20** in timed relationship to the position of the pistons within the cylinders by opening the valves **39** with the valve actuator **41**.

When it is desired to increase the speed of the engine, the operator moves the throttle linkage **35** which simultaneously admits a larger quantity of compressed gas to the distributor **33** from the tank **23** by further opening the regulator valve **31**. The timing of the valve actuator **41** is also advanced through the linkage **104**. Still further, as the speed of the engine **21** increases, the effective length of the rotating contact **83** (FIG. **4**) or **95** (FIG. **6**) increases thereby electrically contacting a wider portion of one of the stationary radial contacts **85** to cause each of the valves **39** to remain open for a longer period of each engine cycle to admit a larger quantity of compressed gas to each of the cylinders **20**.

As can be seen, the combination of the regulating valve **31**, the mechanical advance **104**, and the valve actuator **41**, combine to produce a compressed gas engine which is quickly and efficiently adaptable to various operating speeds. However, all three of the controls need not be employed simultaneously. For example, the mechanical advance **104** could be utilized without the benefit of one of the varying valve actuators **41** but the high speed operation of the engine may not be as efficient. By increasing the duration of each engine cycle over which each of the valves **39** remains open to admit compressed gas to each of the cylinders **20** as the speed increases, conservation of compressed gas during low speed operation and efficient high speed operation are both possible.

After the compressed gas admitted to the cylinder **20** has forced the piston **22** downwardly within the cylinder to drive the shaft **139** of the engine, the piston **22** moves upwardly within the cylinder **20** and forces the expanded gas out through a suitable exhaust valve (not shown) through the adapter plate **103** (if employed) and into the exhaust line **105**. The cool exhaust can then be collected in any suitable arrangement to be compressed and returned to the tank **23** or used for any desired purpose including use as a working fluid in an air conditioning system or as a coolant for oil.

When using the apparatus and method of the present invention to adapt a ordinary internal combustion engine for operation with compressed gas it can be seen that considerable savings in weight are achieved. For example, the ordinary cooling system including a radiator, fan, hoses, etc. can be eliminated since the compressed gas is cooled as it expands in the cylinder. In addition, there are no explosions within the cylinder to generate heat. Further reductions in weight are obtained by employing plastic tubing for the lines which carry the compressed gas between the distributor and the cylinders and for the exhaust lines. Once again, heavy tubing is not required since there is little or no heat generated by the engine of the present invention. In addition, the noise generated by an engine according to the present invention is considerably less than that generated by an ordinary internal combustion engine since there are no explosions taking place within the cylinders.

The principles of preferred embodiments of the present invention have been described in the foregoing specification. However, the invention which is intended to be protected is not to be construed as limited to the particular embodiments disclosed. The embodiments are to be regarded as illustrative rather than restrictive. Variations and changes may be made by others without departing from the spirit of the invention. Accordingly, it is expressly intended that all such variations and changes which fall within the spirit and the scope of the present invention as defined in the appended claims be embraced thereby.

What is claimed is:

1. An apparatus for operating an engine having at least one cylinder and a reciprocating piston therein comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder;

altering means for increasing the duration of each engine cycle over which the valve means admits compressed gas to the at least one cylinder as the speed of the engine increases; and

exhaust means for exhausting gas as the piston subsequently approaches approximately the top dead center position.

2. The apparatus of claim **1** further comprising control means for controlling the amount of compressed gas admitted to the distributor means.

3. The apparatus of claim **1** wherein the valve means is a solenoid valve secured in an opening in the cylinder above the level of the piston at the top dead center position.

4. The apparatus of claims **1** or **2** further comprising means for advancing the timing of the valve means as the speed of the engine increases such that compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

5. The apparatus of claim **4** wherein the means for advancing the timing comprises a mechanical linkage connected to an operator actuated accelerator linkage.

6. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is compressed in a compressor driven by an output shaft of the engine and is returned to the source of compressed gas.

7. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is used to cool transmission fluid for a transmission associated with the engine.

8. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is used as a working fluid in an air conditioning system.

9. The apparatus of claim **6** further comprising first gearing means interposed between the output shaft of the engine and the compressor for increasing the speed at which the compressor is driven.

10. The apparatus of claim **6** further comprising clutch means attached to the compressor both for disengaging the compressor from the output shaft of the engine when a first predetermined pressure at the source of compressed gas is exceeded and for engaging the compressor with the output shaft of the engine when the pressure at the source of compressed gas drops below a second predetermined pressure.

11. The apparatus of claim **9** further comprising means for both disengaging the first gearing means when a predetermined speed of the engine is exceeded and engaging a second gearing means for driving the compressor at a speed slower than the first gearing means when the predetermined speed of the engine is exceeded.

12. The apparatus of claim **1** wherein the valve means is electrically actuated and wherein the altering means comprises:

a rotating member timed with the at least one cylinder and arranged within a housing;

first and second contacts arranged on a first end of the rotating member and on an inside surface of the housing, respectively;

means for increasing the distance of the first contact from the rotational axis of the rotating member as the speed of the engine increases such that the first contact moves radially outwardly within the housing; and

said second contact presenting a longer arc length to the first contact as the distance of the first contact from the rotational axis of the rotating member increases.

13. The apparatus of claim **12** wherein the rotating member comprises an arcuate arm and wherein the means for increasing the distance of the first contact comprises pivotally mounting a second end of the arcuate arm about the axis of rotation of the rotating member and spring means for biasing the first end of the arcuate arm towards a radially inward position whereby the first end of the arcuate arm pivots radially outwardly as the speed of the engine increases.

14. The apparatus of claim **12** wherein the rotating member is axially slidably received on a rotating shaft for co-rotation therewith, said shaft having splines with a radial component in the direction of rotation, and wherein the first contact comprises a flexible contact located on an upper surface of the rotating member, said flexible contact being biased against the inside surface of the housing which carries the second contacts whereby as the speed of the engine increases the rotating member is urged axially along the splined shaft towards the inside surface of the housing such that the flexible contact is forced radially outwardly along the inside surface.

15. The apparatus of claim **12** wherein the second contact comprises of radially extending conductor arranged on an upper inside surface of the housing, said conductor increasing in arc length as the conductor extends radially outwardly from a central portion of the housing.

16. An apparatus for adapting an internal combustion engine for operation with compressed gas, the internal combustion engine having at least one cylinder, a piston reciprocable within the at least one cylinder, intake and exhaust means disposed in the at least one cylinder, and a tapped hole in the at least one cylinder adapted to receive a spark plug, the apparatus comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means arranged in the tapped hole for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder; and

altering means for increasing the duration of each engine cycle over which the valve means remains open to admit the compressed gas as the speed of the engine increases.

17. An apparatus as in claim **16** further comprising first adapter plate means for supporting the distributor means above an intake manifold of the engine, which adaptor plate means allows ambient air to enter through the intake manifold.

18. The apparatus of claim **16** further comprising second adapter plate means for reducing the exit area of the exhaust means.

19. A method of operating an engine on compressed gas, said engine having at least one cylinder and a piston reciprocable therein comprising the steps of:

delivering compressed gas from a source to a distributor;

distributing the compressed gas to the at least one cylinder;

admitting compressed gas to the at least one cylinder through an intake valve when the piston is at approximately a top dad center position;

increasing the duration of each engine cycle over which compressed gas is admitted to the at least one cylinder as the engine speed increases; and

exhausting the remaining gas when the piston subsequently reaches approximately the top dead center position.

20. The method of claim **19** further comprising the step of controlling the amount of compressed gas which is delivered to the distributor.

21. The method of claim **19** further comprising the step of advancing the timing of the opening of the intake valve as the speed of the engine increases.

22. An apparatus for operating an engine having at least one cylinder and a piston reciprocable therein on compressed gas comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

electrically actuated valve means secured in an opening in the at least one cylinder for selectively admitting compressed gas to the at least one cylinder when the piston is in approximately a top dead center position; and

means for advancing the timing of the valve means as the speed of the engine increases whereby compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

[57] **ABSTRACT**

The present invention relates to a method and apparatus for operating an engine having a cylinder and a piston reciprocable therein on compressed gas. The apparatus comprises a source of compressed gas connected to a distributor which distributes the compressed gas to the cylinder. A valve is provided to selectively admit compressed gas to the cylinder when the piston is in an approximately top dead center position. In one embodiment of the present invention the timing of the opening of the valve is advanced such that the compressed gas is admitted to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases. In a further embodiment of the present invention a valve actuator is provided which increases the length of time over which the valve remains open to admit compressed gas to the cylinder as the speed of the engine increases. A still further embodiment of the present invention relates to an apparatus for adapting a conventional internal combustion engine for operation on compressed gas.

METHOD AND APPARATUS FOR OPERATING AN ENGINE ON COMPRESSED GAS

BACKGROUND AND SUMMARY OF THE PRESENT INVENTION

The present invention relates to a method and apparatus for operating an engine using a compressed gas as the motive fluid. More particularly, the present invention relates to a apparatus for adapting a pre-existing internal combustion engine for operation on a compressed gas.

Air pollution is one of the most serious problems facing the world today. One of the major contributors to air pollution is ordinary internal combustion engine which are used in most motor vehicles today. Various devices, including many items mandated by legislation, have been proposed in an attempt to limit the pollutants which an internal combustion engine exhausts to the air. However, most of these devices have met with limited success and are often both prohibitively expensive and complex. A clean alternative to the internal combustion engine is needed to power vehicles and other machinery.

A compressed gas, preferably air, would provide an ideal motive fluid for a engine since it would eliminate the usual pollutants exhausted from an internal combustion engine. An apparatus for converting an internal combustion engine for operation on compressed air is disclosed in U.S. Pat. No. 3,885,387 issued May 27, 1975 to Simington. The Simington patent discloses an apparatus including a source of compressed air and a rotating valve actuator which opens and closes a plurality of mechanical poppet valves. The valves deliver compressed air in timed sequence to the cylinders of an engine through adapters located in the spark plug holes. However, the output speed of an engine of this type is limited by the speed of the mechanical valves and the fact that the length of time over which each of the valves remains open cannot be varied as the speed of the engine increases.

Another apparatus for converting an internal combustion engine for operation on steam or compressed air is disclosed in U.S. Pat. No. 4,102,130 issued July 25, 1978 to Stricklin. The Stricklin patent discloses a device which changes the valve timing of a conventional four stroke engine such that the intake and exhaust valves open once for every revolution of the engine instead of once every other revolution of the engine. A reversing valve is provided which delivers live steam or compressed air to the intake valves and is subsequently reversed to allow the exhaust valves to deliver the expanded steam or air to the atmosphere. A reversing valve of this type however does not provide a reliable apparatus for varying the amount of motive fluid injected into the cylinders when it is desired to increase the speed of the engine. Further, a device of the type disclosed in the Stricklin patent requires the use of multiple reversing valves if the cylinders in a multi-cylinder engine were to be fired sequentially.

Therefore, it is an object of the present invention to provide a reliable method and apparatus for operating an engine or converting an engine for operation with a compressed gas.

A further object of the present invention is to provide a method and apparatus which is effective to deliver a

constantly increasing amount of compressed gas to an engine as the speed of the engine increases.

A still further object of the present invention is to provide a method and apparatus which will operate an engine using compressed gas at a speed sufficient to drive a conventional automobile at highway speeds.

It is still a further object of the present invention to provide a method and apparatus which is readily adaptable to a standard internal combustion engine to convert the internal combustion engine for operation with a compressed gas.

Another object of the invention is to provide a method and apparatus which utilizes cool expanded gas, exhausted from a compressed gas engine, to operate an air conditioning unit and/or an oil cooler.

These and other objects are realized by a method and apparatus according to the present invention for operating an engine having at least one cylinder and a reciprricating piston therein using compressed gas as a motive fluid. The apparatus includes a source of compressed gas and a distributor connected with the source of the compressed gas for distributing the compressed gas to the at least one cylinder. A valve is provided for admitting the compressed gas to the cylinder when the piston is in approximately a top dead center position within the cylinder. An exhaust is provided for exhausting the expanded gas from the cylinder as the piston returns to approximately the top dead center position.

In a preferred embodiment of the present invention a device is provided for varying the duration of each engine cycle over which the valve remains open to admit compressed gas to the cylinder dependent upon the speed of the engine. In a further preferred embodiment of the present invention, an apparatus for advancing the timing of the opening of the valve is arranged to admit the compressed gas to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases.

Further features of the present invention include a valve for controlling the amount of compressed gas admitted to the distributor. Also, a portion of the gas which has been expanded in the cylinder and exhausted through the exhaust valve is delivered to a compressor to be recompressed and returned to the source of compressed gas. A gear train is selectively engagable to drive the compressor at different operating speed depending upon the pressure maintained at the source of compressed air and/or the speed of the engine. Still further, a second portion of the exhaust gas is used to cool a lubricating fluid for the engine or to operate an air conditioning unit.

In a preferred embodiment of the present invention, the valve for admitting compressed gas to the cylinder is electrically actuated. The device for varying the duration of each engine cycle over which the intake valve remains open as the speed of the engine increase comprises a rotating element whose effective length increases as the speed of the engine increases such that a first contact on the rotating element is electrically connected to a second contact for a longer period of each engine cycle. The second contact actuates the valve whereby the valve remains in an open position for a longer period of each engine cycle as the speed of the engine increases.

Still further features of the present invention include an adaptor plate for supporting the distributor above an intake manifold of a conventional internal combustion engine after a carburetor has been removed to allow air

to enter the cylinders of the engine through the intake manifold and conventional intake valves. Another adaptor plate is arranged over an exhaust passageway of the internal combustion engine to reduce the cross-sectional area of the exhaust passageway.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of a method and apparatus for operating an engine according to the present invention will be described with reference to the accompanying drawings wherein like members bear like reference numerals and wherein:

FIG. 1 is a schematic representation of an apparatus according to the present invention arranged on an engine;

FIG. 2 is a side view of one embodiment of a valve actuator according to the present invention;

FIG. 3 is a cross-sectional view taken along the line 3—3 in FIG. 2;

FIG. 4 is a cross-sectional view of a second embodiment of a valve actuator according to the present invention;

FIG. 5 is a view taken along the line 5—5 in FIG. 4;

FIG. 6 is a cross-sectional view of a third embodiment of a valve actuator according to the present invention;

FIG. 7 is a view taken along the line 7—7 in FIG. 6;

FIG. 8 is a cross-sectional view of a gearing unit to drive a compressor according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to FIG. 1, an engine block **21** (shown in phantom) having two banks of cylinders with each bank including cylinders **20** having pistons **22** reciprocable therein (only one of which is shown in phantom) in a conventional manner. While the illustrated engine is a V-8 engine, it will be apparent that the present invention is applicable to an engine having any number of pistons and cylinders with the V-8 engine being utilized for illustration purposes only. A compressed gas tank **23** is provided to store a compressed gas at high pressure. It may also be desirable to include a small electric or gas compressor to provide compressed gas to supplement the compressed gas held in the tank **23**. In a preferred embodiment, the compressed gas is air which can be obtained from any suitable source.

A line **25** transports the gas withdrawn from the tank **23** when a conventional shut off valve **27** is open. In addition, a solenoid valve **29** preferably operated by a suitable key operated switch (not shown) for the engine is also arranged in the line **25**. In normal operation, the valve **27** is maintained open at all times with the solenoid valve **29** operating as a selective shut off valve to start and stop the engine **21** of the present invention.

A suitable regulating valve **31** is arranged downstream from the solenoid valve **29** and is connected by a linkage **33** to a throttle linkage **35** which is operator actuated by any suitable apparatus such as a foot pedal (not shown). The line **25** enters an end of a distributor **33** and is connected to an end of a pipe **35** which is closed at the other end. A plurality of holes, which are equal to the number of cylinders in the engine **21**, are provided on either side of the pipe **35** along the length of the pipe **35**.

When the present invention is used to adapt a conventional internal combustion engine for operation on compressed gas, an adaptor plate **36** is provided to support the distributor **33** in spaced relation from the usual intake opening in the intake manifold of the engine after a conventional carburetor has been removed. In this way, air is permitted to enter the internal combustion engine through the usual passageways and to be admitted to the cylinders through suitable intake valves (not shown). The adaptor plate **36** is secured to the engine block **21** and the distributor **33** by any suitable apparatus, e.g., bolts.

Each of the holes in the pipe **35** is connected in fluid-tight manner to a single line **37**. Each line **37** carries the compressed gas to a single cylinder **20**. In a preferred embodiment, each of the lines **37** is $\frac{1}{2}$ inch high pressure plastic tubing attached through suitable connectors to the distributor **33** and the pipe **35**. Each of the lines **37** is connected to a valve **39** which is secured in an opening provided near the top of each of the cylinders **20**. In the case of a conversion of a standard internal combustion engine, the valves **39** can be conveniently screwed into a tapped hole in the cylinder **20** typically provided for a spark plug of the internal combustion engine. In a preferred embodiment, the valves **39** are solenoid actuated valves in order to provide a fast and reliable opening and closing of the valves **39**.

Each of the valves **39** is energized by a valve actuator **41** through one of a plurality of wires **43**. The valve actuator **41** is driven by a shaft of the engine similar to the drive for a conventional distributor of an internal combustion engine. That is, a shaft **55** of the valve actuator **41** is driven in synchronism with the engine **21** at one half the speed of the engine **21**.

A first embodiment of the valve actuator **41** (FIGS. **2** and **3**) receives electrical power through a wire **45** which is energized in a suitable manner by a battery, and a coil if necessary (not shown) as is conventional in an internal combustion engine. The wire **45** is attached to a central post **47** by a nut **49**. The post **47** is connected to a conducting plate **51** arranged within a housing **53** for the valve actuator **41**. Within the housing **53**, the shaft **55** has an insulating element **57** secured to an end of the shaft **55** for co-rotation therewith when the shaft **55** is driven by the engine **21**. A first end of a flexible contact **59** is continuously biased against the conducting plate **51** to receive electricity from the battery or another suitable source. A second end of the contact **59** is connected to a conducting sleeve **60** which is in constant contact with a spring biased contact **61** which is arranged within the sleeve **60**. The contact **61** is biased by a spring **63** which urges the contact **61** towards a side wall of the housing **53**.

With reference to FIG. 3, a plurality of contacts **65** are spaced from one another and are arranged around the periphery of the housing **53** at the same level as the spring biased contact **61**. Each contact **65** is electrically connected to a post **67** which extends outside of the housing **53**. The number of contacts **65** is equal to the number of cylinders in the engine **21**. One of the wires **43**, which actuate the valves **39**, is secured to each of the posts **67**.

In operation, as the shaft **55** rotates in synchronism with the engine **21**, the insulating element **57** rotates and electricity is ultimately delivered to successive ones of the contacts **65** and wires **43** through the spring biased contact **61** and the flexible contact **59**. In this way, each of the electrical valves **39** is actuated and opened in the proper timed sequence to admit compressed gas to each of the cylinders **20** to drive the pistons **22** therein on a downward stroke.

The embodiment illustrated in FIGS. **2** and **3** is effective to actuate each of the valves **39** to remain open for a long enough period of time to admit sufficient compressed gas to each of the cylinders **20** of the engine **21** to drive the engine **21**. The length of each of the contacts **65** around the periphery of the housing **53** is sufficient to permit the speed of the engine to be increased when desired by the operator by moving the throttle linkage **35** which actuates the linkage **33** to further open the regulating valve **31** to admit more compressed gas from the tank **23** to the distributor **33**. However, it has been found that the amount of air admitted by the valves **39** when using the first embodiment of the valve actuator **41** (FIGS. **2** and **3**) is substantially more than required to operate the engine **21** at an idling speed. Therefore, it may be desirable to provide a valve actuator **41** which is capable of varying the duration of each engine cycle over which the solenoid valves **39** are actuated, i.e., remain open to admit compressed gas, as the speed of the engine **21** is varied.

A second embodiment of a valve actuator **41** which is capable of varying the duration of each engine cycle over which each of the valves **39** remains open to admit compressed gas to the cylinders **20** dependent upon the speed of the engine **21** will be described with reference to FIGS. **4** and **5** wherein members corresponding to those of FIGS. **2** and **3** bear like reference numerals. The wire **45** from the electrical source is secured to the post **47** by the nut **49**. The post **47** has a annular contact ring **69** electrically connected to an end of the post **47** and arranged within the housing **53**. The shaft **55** rotates at one half the speed of the engine as in the embodiment of FIGS. **2** and **3**.

At an upper end of the shaft **55**, a splined section **71** slidably receives an insulating member **73**. The splined section **71** of the shaft **55** positively holds the insulating member **73** for co-rotation therewith but permits the insulating member **73** to slide axially along the length of the splined section **71**. Near the shaft **55**, a conductive sleeve **72** is arranged in a bore **81** in an upper surface of the insulating element **73** generally parallel to the splined section **71**. A contact **75**, biased towards the annular contact ring **69** by a spring **77**, is arranged within the conductive sleeve **72** in contact therewith. The conductive sleeve **72** also contacts a conductor **79** at a base of the bore **81**.

The conductor **79** extends to the upper surface of the insulating element **73** near an outer periphery of the insulating element **73** where the conductor **79** is electrically connected to a flexible contact **83**. The flexible contact **83** selectively engages a plurality of radial contacts **85** arranged on an upper inside surface of the housing **53**. A weak spring **87** arranged around the splined section **71** engages a stop member **89** secured on the shaft **55** and the insulating element **73** to slightly bias the insulating element **73** towards the upper inside surface of the housing **53** to ensure contact between the flexible contact **83** and the upper inside surface of the housing **53**. As best seen in FIG. **5**, the radial contacts **85** on the upper inside surface of the housing **53** are arranged generally in the form of radial spokes extending from the center of the housing **53** with the number of contacts being equal to the number of cylinders **20** in the engine **21**. The number of degrees covered by each of the radial contacts **85** gradually increases as the distance from the center of the upper inside surface of the housing **53** increases.

In operation of the device of FIGS. **4** and **5**, as the shaft **55** rotates, electricity flows along a path through the wire **45** down through post **47** to the annular contact member **69** which is in constant contact with the spring biased contact **75**. The electrical current passes through the conductive sleeve **72** to the conductor **79** and then to the flexible contact **83**. As the flexible contact **83** rotates along with the insulating member **73** and the shaft **55**, the tip of the flexible contact **83** successively engages each of the radial contacts **85** on the upper inside of the housing **53**. As the speed of the shaft **55** increases, the insulating member **73** and the flexible contact **83** attached thereto move upwardly along the splined section **71** of the shaft **55** due to the radial component of the splines in the direction of rotation under the influence of centrifugal force. As the insulating member **73** moves upwardly, the flexible contact **83** is bent such that the tip of the contact **83** extends further radially outwardly from the center of the housing **53** (as seen in phantom lines in FIG. **4**). In other words, the effective length of the flexible contact **83** increases as the speed of the engine **21** increases.

As the flexible contact **83** is bent and the tip of the contact **83** moves outwardly, the tip remains in contact with each of the radial contacts **85** for a longer period of each engine cycle due to the increased angular width of the radial contacts with increasing distance from the center of the housing **53**. In this way, the length of time over which each of the valves **39** remains open is increased as the speed of the engine is increased. Thus, a larger quantity of compressed gas or air is injected into the cylinders as the speed increases. Conversely, as the speed decreases and the insulating member **73** moves downwardly along the splined section **71**, a minimum quantity of air is injected into the cylinder due to the shorter length of the individual radial contact **85** which is in contact with the flexible contact **83**. In this way, the amount of compressed gas that is used during idling of the engine **21** is at a minimum whereas the amount of compressed gas which is required to increase the speed of the engine **21** to a level suitable to drive a vehicle on a highway is readily available.

With reference to FIGS. **6** and **7**, a third embodiment of a valve actuator **41** according to the present invention includes an arcuate insulating element **91** having a first end pivotally secured by any suitable device such as screw **92** to the shaft **55** for co-rotation with the shaft **55**. The screw **92** is screwed into a tapped hole in the insulating element **91** such that a tab **94** at an end of the screw **92** engages a groove **96** provided in the shaft **55**. In this way, the insulating element **91** positively rotates with the shaft **55**. However, as the shaft **55** rotates faster, a second end **98** of the insulating element **91** is permitted to pivot outwardly under the influence of centrifugal force because of the groove **96** provided in the shaft **55**. A spring **93** connected between the second end **98** of the element **91** and the shaft **55** urges the second end of the element **91** towards the center of the housing **53**.

A contact **99** similar to the contact **59** (FIG. **2**) is arranged such that one end of the contact **99** is in constant contact with the conducting plate **51** located centrally within the housing **53**. The other end of the contact **99** engages a conductive sleeve **101** arranged in bore **102**. A contact element **95** is arranged in the conductive sleeve **101** in constant contact with the sleeve **101**. The bore **102** is arranged generally parallel to the shaft **55** near the second end of the arcuate insulating

element **91**. The contact **95** is biased by a spring **97** towards the upper inside surface of the housing **53** for selective contact with each of the plurality of radial contacts **85** which increase in arc length towards the outer peripheral surface of the housing **53** (FIG. **6**).

In operation of the device of FIGS. **6** and **7**, as the shaft **55** rotates the arcuate insulating element **91** rotates with the shaft **55** and the second end **98** of the insulating element **91** tends to pivot about the shaft **55** due to centrifugal force. Thus, as the effective length of the contact **95** increases, i.e., as the arcuate insulating element **91** pivots further outwardly, the number of degrees of rotation over which the contact **95** is in contact with each of the radial contacts **85** on the upper inside surface of the housing **53** increases thereby permitting each of the valves **39** to remain open for a longer period of each engine cycle to admit more compressed gas to the respective cylinder **20** to further increase the speed of the engine **21**.

With reference to FIG. **1**, a mechanical advance linkage **104** which is connected to the throttle linkage **35**, advances the initiation of the opening of each valve **39** such that compressed gas is injected into the respective cylinder further before the piston **22** in the respective cylinder **20** reaches a top dead center position as the speed of the engine is increased by moving the throttle linkage **35**. The advance linkage **104** is similar to a conventional standard mechanical advance employed on an internal combustion engine. In other words, the linkage **104** varies the relationship between the angular positions of a point on the shaft **55** and a point on the housing **53** containing the contacts. Alternatively, a conventional vacuum advance could also be employed. By advancing the timing of the opening of the valves **39**, the speed of the engine can more easily be increased.

The operation of the engine cycle according to the present invention will now be described. The compressed gas injected into each cylinder of the engine **21** drives the respective piston **22** downward to drive a conventional crankshaft (not shown). The movement of the piston downwardly causes the compressed gas to expand rapidly and cool. As the piston **22** begins to move upwardly in the cylinder **20** a suitable exhaust valve (not shown) arranged to close an exhaust passageway is opened by any suitable apparatus. The expanded gas is then expelled through the exhaust passageway. As the piston **22** again begins to move downwardly a suitable intake valve opens to admit ambient air to the cylinder. The intake valve closes and the ambient air is compressed on the subsequent upward movement of the piston until the piston reaches approximately the top dead center position at which time the compressed gas is again injected into the cylinder **20** to drive the piston **22** downward and the cycle begins anew.

In the case of adapting a conventional internal combustion engine for operation on compressed gas, a plurality of plates **103** are preferably arranged over an end of the exhaust passageways in order to reduce the outlet size of the exhaust passageways of the conventional internal combustion engine. In the illustrated embodiment, a single plate having an opening in the center is bolted to the outside exhaust passageway on each bank of the V-8 engine while another single plate having two openings therein is arranged with one opening over each of the interior exhaust passageways on each bank of the V-8 engine. A line **105** is suitably attached to each of the adaptor places to carry the exhaust to an appropriate location. In a preferred embodiment, the exhaust lines **105** are 1½" plastic tubing.

In a preferred embodiment, the exhaust lines **105** of one bank of the V-8 engine are collected in a line **107** and fed to an inlet of a compressor **109**. The pressure of the exhaust gas emmanating from the engine **21** according to the present invention is approximately 25 p.s.i. In this way, the compressor **109** does not have to pull the exhaust into the compressor since the gas exhausted from the engine **21** is at a positive pressure. The positive pressure of the incoming fluid increases the efficiency and reduces wear on the compressor **109**. The exhaust gas is compressed in the compressor **109** and returned through a line **111** and a check valve **113** to the compressed gas storage tank **23**. The check valve **113** prevents the flow of compressed gas stored in the tank **23** back towards the compressor **109**.

A suitable pressure sensor **115** is arranged at an upper end of the tank **23** and sends a signal along a line **117** when the pressure exceeds a predetermined level and when the pressure drops below a predetermined level. The line **117** controls an electrically actuated clutch **119** disposed at a front end of the compressor **109**. The clutch **119** is operative to engage and disengage the compressor **109** from a drive pulley **121**. Also, the signal carried by the line **117** actuates a suitable valve **123** arranged on a compressor housing **125** to exhaust the air entering the compressor housing **125** from the line **107** when the clutch **119** has disengaged the compressor **109** from the drive pully **121**.

In a preferred embodiment, when the pressure is the tank **23** reaches approximately 600 p.s.i., the clutch **119** is disengaged and the compressor **109** is deactivated and the valve **123** is opened to exhaust the expanded gas delivered to the compressor **109** from the line **107** to the atmosphere. When the pressure within the tank **23** drops below approximately 500 p.s.i., the sensor **115** sends a signal to engage the clutch **119** and close the valve **123**, thereby operating the compressor **109** for supplying the tank **23** with compressed gas.

The pulley **121** which drives the compressor **109** through the clutch **119** is driven by a belt **127** which is driven by a pulley **129** which operates through a gear box **131**. With reference to FIGS. **1** and **8**, a second pulley **133** on the gear box is driven by a belt **135** from a pulley **137** arranged on a drive shaft **139** of the engine **21**. The pulley **137** drives a splined shaft **140** which has a first gear **141** and a second larger gear **143** arranged thereon for rotation with the splined shaft **140**. The splined shaft **140** permits axial movement of the gears **141** and **143** along the shaft **140**.

In normal operation (as seen in FIG. **8**), the first gear **141** engages a third gear **145** arranged on a shaft **147** which drives the pulley **129**. The shafts **140** and **147** are arranged in suitable bearings **149** arranged at each end thereof. When the speed of the engine **21** drops below a predetermined level, a suitable sensor **151** responsive to the speed of the drive shaft **139** of the engine **21** generates a signal which is transmitted through a line **153** to a solenoid actuator **155** arranged within the gear box **131**. The solenoid actuator **155** moves the first and second gears **141**, **143** axially along the splined shaft **140** to the right as seen in FIG. **8** such that the second, larger gear **143** engages a fourth smaller gear **157** which is arranged on the shaft **147**. The ratio of the second gear **143** to the fourth gear **157** is preferably approximately 3 to 1.

In this way, when the speed of the engine **21** drops below the predetermined level as sensed by the sensor **151** (which predetermined level is insufficient to drive the compressor **109** at a speed sufficient to generate the 500-600 pounds of pressure which is preferably in the tank **23**), the solenoid actuator **155** is energized to slide the gears **143**, **141** axially along the splined shaft **140** so that the second, larger gear **143** engages the fourth, smaller gear **157** to drive the pulley **129** and hence the compressor **109** at a higher rate of speed to generate the desired pressure. When the speed of the engine increases above the predetermined level, in a preferred embodiment approximately 1500 rpm, the solenoid actuator **155** is deactivated by the sensor **151** thereby moving the gears **143** and **141** to the left as seen in FIG. **8** such that the first gear **141** re-engages with the third gear **145** to effectuate a 1 to 1 ratio between the output shaft **139** of the engine **21** and the pulley **129**.

The other bank of the V-8 engine has its exhaust ports arranged with adapter plates **103** similar to those on the first bank. However, the exhaust from this bank of the engine **21** is not collected and circulated through the compressor **109**. In a preferred embodiment, a portion of the exhaust is collected in a line **159** and fed to an enlarged chamber **161**. A second fluid is fed through a line **163** into the chamber **161** to be cooled by the cool exhaust emmanating from the engine **21** in the line **159**. The second fluid in the line **163** may be either transmission fluid contained in a transmission associated with the engine **21** or a portion of the oil used to lubricate the engine **21**. A second portion of the exhaust from the second bank of the V-8 engine is removed from the line **159** in a line **165** and used as a working fluid in an air conditioning system or for any other suitable use.

It should be noted that the particular arrangement utilized for collecting and distributing the gas exhausted from the engine **21** would be determined by the use for which the engine is employed. In other words, it may be advantageous to rearrange the exhaust tubing such that a larger or smaller percentage of the exhaust is routed through the compressor **109**. It should also be noted that since the exhaust lines **105** are plastic tubing, a rearrangement of the lines for a different purpose is both simple and inexpensive.

In operation of the engine of the present invention, the engine **21** is started by energizing the solenoid valve **29** and any suitable starting device (not shown), e.g., a conventional electric starter as used on an internal combustion engine. Compressed gas from the full tank **23** flows through the line **25** and a variable amount of the compressed gas is admitted to the distributor **33** by controlling the regulator valve **31** through the linkage **33** and the operator actuated throttle linkage **35**. The compressed gas is distributed to each of the lines **37** which lead to the individual cylinders **20**. The compressed gas is admitted to each of the cylinders **20** in timed relationship to the position of the pistons within the cylinders by opening the valves **39** with the valve actuator **41**.

When it is desired to increase the speed of the engine, the operator moves the throttle linkage **35** which simultaneously admits a larger quantity of compressed gas to the distributor **33** from the tank **23** by further opening the regulator valve **31**. The timing of the valve actuator **41** is also advanced through the linkage **104**. Still further, as the speed of the engine **21** increases, the effective length of the rotating contact **83** (FIG. 4) or **95** (FIG. 6) increases thereby electrically contacting a wider portion of one of the stationary radial contacts **85** to cause each of the valves **39** to remain open for a longer period of each engine cycle to admit a larger quantity of compressed gas to each of the cylinders **20**.

As can be seen, the combination of the regulating valve **31**, the mechanical advance **104**, and the valve actuator **41**, combine to produce a compressed gas engine which is quickly and efficiently adaptable to various operating speeds. However, all three of the controls need not be employed simultaneously. For example, the mechanical advance **104** could be utilized without the benefit of one of the varying valve actuators **41** but the high speed operation of the engine may not be as efficient. By increasing the duration of each engine cycle over which each of the valves **39** remains open to admit compressed gas to each of the cylinders **20** as the speed increases, conservation of compressed gas during low speed operation and efficient high speed operation are both possible.

After the compressed gas admitted to the cylinder **20** has forced the piston **22** downwardly within the cylinder to drive the shaft **139** of the engine, the piston **22** moves upwardly within the cylinder **20** and forces the expanded gas out through a suitable exhaust valve (not shown) through the adapter plate **103** (if employed) and into the exhaust line **105**. The cool exhaust can then be collected in any suitable arrangement to be compressed and returned to the tank **23** or used for any desired purpose including use as a working fluid in an air conditioning system or as a coolant for oil.

When using the apparatus and method of the present invention to adapt a ordinary internal combustion engine for operation with compressed gas it can be seen that considerable savings in weight are achieved. For example, the ordinary cooling system including a radiator, fan, hoses, etc. can be eliminated since the compressed gas is cooled as it expands in the cylinder. In addition, there are no explosions within the cylinder to generate heat. Further reductions in weight are obtained by employing plastic tubing for the lines which carry the compressed gas between the distributor and the cylinders and for the exhaust lines. Once again, heavy tubing is not required since there is little or no heat generated by the engine of the present invention. In addition, the noise generated by an engine according to the present invention is considerably less than that generated by an ordinary internal combustion engine since there are no explosions taking place within the cylinders.

The principles of preferred embodiments of the present invention have been described in the foregoing specification. However, the invention which is intended to be protected is not to be construed as limited to the particular embodiments disclosed. The embodiments are to be regarded as illustrative rather than restrictive. Variations and changes may be made by others without departing from the spirit of the invention. Accordingly, it is expressly intended that all such variations and changes which fall within the spirit and the scope of the present invention as defined in the appended claims be embraced thereby.

What is claimed is:

1. An apparatus for operating an engine having at least one cylinder and a reciprocating piston therein comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder;

altering means for increasing the duration of each engine cycle over which the valve means admits compressed gas to the at least one cylinder as the speed of the engine increases; and

exhaust means for exhausting gas as the piston subsequently approaches approximately the top dead center position.

2. The apparatus of claim 1 further comprising control means for controlling the amount of compressed gas admitted to the distributor means.

3. The apparatus of claim 1 wherein the valve means is a solenoid valve secured in an opening in the cylinder above the level of the piston at the top dead center position.

4. The apparatus of claims 1 or 2 further comprising means for advancing the timing of the valve means as the speed of the engine increases such that compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

5. The apparatus of claim 4 wherein the means for advancing the timing comprises a mechanical linkage connected to an operator actuated accelerator linkage.

6. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is compressed in a compressor driven by an output shaft of the engine and is returned to the source of compressed gas.

7. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is used to cool transmission fluid for a transmission associated with the engine.

8. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is used as a working fluid in an air conditioning system.

9. The apparatus of claim 6 further comprising first gearing means interposed between the output shaft of the engine and the compressor for increasing the speed at which the compressor is driven.

10. The apparatus of claim 6 further comprising clutch means attached to the compressor both for disengaging the compressor from the output shaft of the engine when a first predetermined pressure at the source of compressed gas is exceeded and for engaging the compressor with the output shaft of the engine when the pressure at the source of compressed gas drops below a second predetermined pressure.

11. The apparatus of claim 9 further comprising means for both disengaging the first gearing means when a predetermined speed of the engine is exceeded and engaging a second gearing means for driving the compressor at a speed slower than the first gearing means when the predetermined speed of the engine is exceeded.

12. The apparatus of claim 1 wherein the valve means is electrically actuated and wherein the altering means comprises:

a rotating member timed with the at least one cylinder and arranged within a housing;

first and second contacts arranged on a first end of the rotating member and on an inside surface of the housing, respectively;

means for increasing the distance of the first contact from the rotational axis of the rotating member as the speed of the engine increases such that the first contact moves radially outwardly within the housing; and

said second contact presenting a longer arc length to the first contact as the distance of the first contact from the rotational axis of the rotating member increases.

13. The apparatus of claim 12 wherein the rotating member comprises an arcuate arm and wherein the means for increasing the distance of the first contact comprises pivotally mounting a second end of the arcuate arm about the axis of rotation of the rotating member and spring means for biasing the first end of the arcuate arm towards a radially inward position whereby the first end of the arcuate arm pivots radially outwardly as the speed of the engine increases.

14. The apparatus of claim 12 wherein the rotating member is axially slidably received on a rotating shaft for co-rotation therewith, said shaft having splines with a radial component in the direction of rotation, and wherein the first contact comprises a flexible contact located on an upper surface of the rotating member, said flexible contact being biased against the inside surface of the housing which carries the second contacts whereby as the speed of the engine increases the rotating member is urged axially along the splined shaft towards the inside surface of the housing such that the flexible contact is forced radially outwardly along the inside surface.

15. The apparatus of claim 12 wherein the second contact comprises of radially extending conductor arranged on an upper inside surface of the housing, said conductor increasing in arc length as the conductor extends radially outwardly from a central portion of the housing.

16. An apparatus for adapting an internal combustion engine for operation with compressed gas, the internal combustion engine having at least one cylinder, a piston reciprocable within the at least one cylinder, intake and exhaust means disposed in the at least one cylinder, and a tapped hole in the at least one cylinder adapted to receive a spark plug, the apparatus comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means arranged in the tapped hole for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder; and

altering means for increasing the duration of each engine cycle over which the valve means remains open to admit the compressed gas as the speed of the engine increases.

17. An apparatus as in claim 16 further comprising first adapter plate means for supporting the distributor means above an intake manifold of the engine, which adaptor plate means allows ambient air to enter through the intake manifold.

18. The apparatus of claim 16 further comprising second adapter plate means for reducing the exit area of the exhaust means.

19. A method of operating an engine on compressed gas, said engine having at least one cylinder and a piston reciprocable therein comprising the steps of:

delivering compressed gas from a source to a distributor;

distributing the compressed gas to the at least one cylinder;

admitting compressed gas to the at least one cylinder through an intake valve when the piston is at approximately a top dad center position;

increasing the duration of each engine cycle over which compressed gas is admitted to the at least one cylinder as the engine speed increases; and

exhausting the remaining gas when the piston subsequently reaches approximately the top dead center position.

20. The method of claim **19** further comprising the step of controlling the amount of compressed gas which is delivered to the distributor.

21. The method of claim **19** further comprising the step of advancing the timing of the opening of the intake valve as the speed of the engine increases.

22. An apparatus for operating an engine having at least one cylinder and a piston reciprocable therein on compressed gas comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

electrically actuated valve means secured in an opening in the at least one cylinder for selectively admitting compressed gas to the at least one cylinder when the piston is in approximately a top dead center position; and

means for advancing the timing of the valve means as the speed of the engine increases whereby compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

[57] **ABSTRACT**

The present invention relates to a method and apparatus for operating an engine having a cylinder and a piston reciprocable therein on compressed gas. The apparatus comprises a source of compressed gas connected to a distributor which distributes the compressed gas to the cylinder. A valve is provided to selectively admit compressed gas to the cylinder when the piston is in an approximately top dead center position. In one embodiment of the present invention the timing of the opening of the valve is advanced such that the compressed gas is admitted to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases. In a further embodiment of the present invention a valve actuator is provided which increases the length of time over which the valve remains open to admit compressed gas to the cylinder as the speed of the engine increases. A still further embodiment of the present invention relates to an apparatus for adapting a conventional internal combustion engine for operation on compressed gas.

METHOD AND APPARATUS FOR OPERATING AN ENGINE ON COMPRESSED GAS

BACKGROUND AND SUMMARY OF THE PRESENT INVENTION

The present invention relates to a method and apparatus for operating an engine using a compressed gas as the motive fluid. More particularly, the present invention relates to a apparatus for adapting a pre-existing internal combustion engine for operation on a compressed gas.

Air pollution is one of the most serious problems facing the world today. One of the major contributors to air pollution is ordinary internal combustion engine which are used in most motor vehicles today. Various devices, including many items mandated by legislation, have been proposed in an attempt to limit the pollutants which an internal combustion engine exhausts to the air. However, most of these devices have met with limited success and are often both prohibitively expensive and complex. A clean alternative to the internal combustion engine is needed to power vehicles and other machinery.

A compressed gas, preferably air, would provide an ideal motive fluid for a engine since it would eliminate the usual pollutants exhausted from an internal combustion engine. An apparatus for converting an internal combustion engine for operation on compressed air is disclosed in U.S. Pat. No. 3,885,387 issued May 27, 1975 to Simington. The Simington patent discloses an apparatus including a source of compressed air and a rotating valve actuator which opens and closes a plurality of mechanical poppet valves. The valves deliver compressed air in timed sequence to the cylinders of an engine through adapters located in the spark plug holes. However, the output speed of an engine of this type is limited by the speed of the mechanical valves and the fact that the length of time over which each of the valves remains open cannot be varied as the speed of the engine increases.

Another apparatus for converting an internal combustion engine for operation on steam or compressed air is disclosed in U.S. Pat. No. 4,102,130 issued July 25, 1978 to Stricklin. The Stricklin patent discloses a device which changes the valve timing of a conventional four stroke engine such that the intake and exhaust valves open once for every revolution of the engine instead of once every other revolution of the engine. A reversing valve is provided which delivers live steam or compressed air to the intake valves and is subsequently reversed to allow the exhaust valves to deliver the expanded steam or air to the atmosphere. A reversing valve of this type however does not provide a reliable apparatus for varying the amount of motive fluid injected into the cylinders when it is desired to increase the speed of the engine. Further, a device of the type disclosed in the Stricklin patent requires the use of multiple reversing valves if the cylinders in a multi-cylinder engine were to be fired sequentially.

Therefore, it is an object of the present invention to provide a reliable method and apparatus for operating an engine or converting an engine for operation with a compressed gas.

A further object of the present invention is to provide a method and apparatus which is effective to deliver a constantly increasing amount of compressed gas to an engine as the speed of the engine increases.

A still further object of the present invention is to provide a method and apparatus which will operate an engine using compressed gas at a speed sufficient to drive a conventional automobile at highway speeds.

It is still a further object of the present invention to provide a method and apparatus which is readily adaptable to a standard internal combustion engine to convert the internal combustion engine for operation with a compressed gas.

Another object of the invention is to provide a method and apparatus which utilizes cool expanded gas, exhausted from a compressed gas engine, to operate an air conditioning unit and/or an oil cooler.

These and other objects are realized by a method and apparatus according to the present invention for operating an engine having at least one cylinder and a reciprocating piston therein using compressed gas as a motive fluid. The apparatus includes a source of compressed gas and a distributor connected with the source of the compressed gas for distributing the compressed gas to the at least one cylinder. A valve is provided for admitting the compressed gas to the cylinder when the piston is in approximately a top dead center position within the cylinder. An exhaust is provided for exhausting the expanded gas from the cylinder as the piston returns to approximately the top dead center position.

In a preferred embodiment of the present invention a device is provided for varying the duration of each engine cycle over which the valve remains open to admit compressed gas to the cylinder dependent upon the speed of the engine. In a further preferred embodiment of the present invention, an apparatus for advancing the timing of the opening of the valve is arranged to admit the compressed gas to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases.

Further features of the present invention include a valve for controlling the amount of compressed gas admitted to the distributor. Also, a portion of the gas which has been expanded in the cylinder and exhausted through the exhaust valve is delivered to a compressor to be recompressed and returned to the source of compressed gas. A gear train is selectively engagable to drive the compressor at different operating speed depending upon the pressure maintained at the source of compressed air and/or the speed of the engine. Still further, a second portion of the exhaust gas is used to cool a lubricating fluid for the engine or to operate an air conditioning unit.

In a preferred embodiment of the present invention, the valve for admitting compressed gas to the cylinder is electrically actuated. The device for varying the duration of each engine cycle over which the intake valve remains open as the speed of the engine increase comprises a rotating element whose effective length increases as the speed of the engine increases such that a first contact on the rotating element is electrically connected to a second contact for a longer period of each engine cycle. The second contact actuates the valve whereby the valve remains in an open position for a longer period of each engine cycle as the speed of the engine increases.

Still further features of the present invention include an adaptor plate for supporting the distributor above an intake manifold of a conventional internal combustion engine after a carburetor has been removed to allow air

to enter the cylinders of the engine through the intake manifold and conventional intake valves. Another adaptor plate is arranged over an exhaust passageway of the internal combustion engine to reduce the cross-sectional area of the exhaust passageway.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of a method and apparatus for operating an engine according to the present invention will be described with reference to the accompanying drawings wherein like members bear like reference numerals and wherein:

FIG. 1 is a schematic representation of an apparatus according to the present invention arranged on an engine;

FIG. 2 is a side view of one embodiment of a valve actuator according to the present invention;

FIG. 3 is a cross-sectional view taken along the line 3—3 in FIG. 2;

FIG. 4 is a cross-sectional view of a second embodiment of a valve actuator according to the present invention;

FIG. 5 is a view taken along the line 5—5 in FIG. 4;

FIG. 6 is a cross-sectional view of a third embodiment of a valve actuator according to the present invention;

FIG. 7 is a view taken along the line 7—7 in FIG. 6;

FIG. 8 is a cross-sectional view of a gearing unit to drive a compressor according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to FIG. 1, an engine block **21** (shown in phantom) having two banks of cylinders with each bank including cylinders **20** having pistons **22** reciprocable therein (only one of which is shown in phantom) in a conventional manner. While the illustrated engine is a V-8 engine, it will be apparent that the present invention is applicable to an engine having any number of pistons and cylinders with the V-8 engine being utilized for illustration purposes only. A compressed gas tank **23** is provided to store a compressed gas at high pressure. It may also be desirable to include a small electric or gas compressor to provide compressed gas to supplement the compressed gas held in the tank **23**. In a preferred embodiment, the compressed gas is air which can be obtained from any suitable source.

A line **25** transports the gas withdrawn from the tank **23** when a conventional shut off valve **27** is open. In addition, a solenoid valve **29** preferably operated by a suitable key operated switch (not shown) for the engine is also arranged in the line **25**. In normal operation, the valve **27** is maintained open at all times with the solenoid valve **29** operating as a selective shut off valve to start and stop the engine **21** of the present invention.

A suitable regulating valve **31** is arranged downstream from the solenoid valve **29** and is connected by a linkage **33** to a throttle linkage **35** which is operator actuated by any suitable apparatus such as a foot pedal (not shown). The line **25** enters an end of a distributor **33** and is connected to an end of a pipe **35** which is closed at the other end. A plurality of holes, which are equal to the number of cylinders in the engine **21**, are provided on either side of the pipe **35** along the length of the pipe **35**.

When the present invention is used to adapt a conventional internal combustion engine for operation on compressed gas, an adaptor plate **36** is provided to support the distributor **33** in spaced relation from the usual intake opening in the intake manifold of the engine after a conventional carburetor has been removed. In this way, air is permitted to enter the internal combustion engine through the usual passageways and to be admitted to the cylinders through suitable intake valves (not shown). The adaptor plate **36** is secured to the engine block **21** and the distributor **33** by any suitable apparatus, e.g., bolts.

Each of the holes in the pipe **35** is connected in fluid-tight manner to a single line **37**. Each line **37** carries the compressed gas to a single cylinder **20**. In a preferred embodiment, each of the lines **37** is $\frac{1}{2}$ inch high pressure plastic tubing attached through suitable connectors to the distributor **33** and the pipe **35**. Each of the lines **37** is connected to a valve **39** which is secured in an opening provided near the top of each of the cylinders **20**. In the case of a conversion of a standard internal combustion engine, the valves **39** can be conveniently screwed into a tapped hole in the cylinder **20** typically provided for a spark plug of the internal combustion engine. In a preferred embodiment, the valves **39** are solenoid actuated valves in order to provide a fast and reliable opening and closing of the valves **39**.

Each of the valves **39** is energized by a valve actuator **41** through one of a plurality of wires **43**. The valve actuator **41** is driven by a shaft of the engine similar to the drive for a conventional distributor of an internal combustion engine. That is, a shaft **55** of the valve actuator **41** is driven in synchronism with the engine **21** at one half the speed of the engine **21**.

A first embodiment of the valve actuator **41** (FIGS. 2 and 3) receives electrical power through a wire **45** which is energized in a suitable manner by a battery, and a coil if necessary (not shown) as is conventional in an internal combustion engine. The wire **45** is attached to a central post **47** by a nut **49**. The post **47** is connected to a conducting plate **51** arranged within a housing **53** for the valve actuator **41**. Within the housing **53**, the shaft **55** has an insulating element **57** secured to an end of the shaft **55** for co-rotation therewith when the shaft **55** is driven by the engine **21**. A first end of a flexible contact **59** is continuously biased against the conducting plate **51** to receive electricity from the battery or another suitable source. A second end of the contact **59** is connected to a conducting sleeve **60** which is in constant contact with a spring biased contact **61** which is arranged within the sleeve **60**. The contact **61** is biased by a spring **63** which urges the contact **61** towards a side wall of the housing **53**.

With reference to FIG. 3, a plurality of contacts **65** are spaced from one another and are arranged around the periphery of the housing **53** at the same level as the spring biased contact **61**. Each contact **65** is electrically connected to a post **67** which extends outside of the housing **53**. The number of contacts **65** is equal to the number of cylinders in the engine **21**. One of the wires **43**, which actuate the valves **39**, is secured to each of the posts **67**.

In operation, as the shaft **55** rotates in synchronism with the engine **21**, the insulating element **57** rotates and electricity is ultimately delivered to successive ones of the contacts **65** and wires **43** through the spring biased contact **61** and the flexible contact **59**. In this way, each of the electrical valves **39** is actuated and opened in the proper timed sequence to admit compressed gas to each of the cylinders **20** to drive the pistons **22** therein on a downward stroke.

The embodiment illustrated in FIGS. 2 and 3 is effective to actuate each of the valves 39 to remain open for a long enough period of time to admit sufficient compressed gas to each of the cylinders 20 of the engine 21 to drive the engine 21. The length of each of the contacts 65 around the periphery of the housing 53 is sufficient to permit the speed of the engine to be increased when desired by the operator by moving the throttle linkage 35 which actuates the linkage 33 to further open the regulating valve 31 to admit more compressed gas from the tank 23 to the distributor 33. However, it has been found that the amount of air admitted by the valves 39 when using the first embodiment of the valve actuator 41 (FIGS. 2 and 3) is substantially more than required to operate the engine 21 at an idling speed. Therefore, it may be desirable to provide a valve actuator 41 which is capable of varying the duration of each engine cycle over which the solenoid valves 39 are actuated, i.e., remain open to admit compressed gas, as the speed of the engine 21 is varied.

A second embodiment of a valve actuator 41 which is capable of varying the duration of each engine cycle over which each of the valves 39 remains open to admit compressed gas to the cylinders 20 dependent upon the speed of the engine 21 will be described with reference to FIGS. 4 and 5 wherein members corresponding to those of FIGS. 2 and 3 bear like reference numerals. The wire 45 from the electrical source is secured to the post 47 by the nut 49. The post 47 has a annular contact ring 69 electrically connected to an end of the post 47 and arranged within the housing 53. The shaft 55 rotates at one half the speed of the engine as in the embodiment of FIGS. 2 and 3.

At an upper end of the shaft 55, a splined section 71 slidably receives an insulating member 73. The splined section 71 of the shaft 55 positively holds the insulating member 73 for co-rotation therewith but permits the insulating member 73 to slide axially along the length of the splined section 71. Near the shaft 55, a conductive sleeve 72 is arranged in a bore 81 in an upper surface of the insulating element 73 generally parallel to the splined section 71. A contact 75, biased towards the annular contact ring 69 by a spring 77, is arranged within the conductive sleeve 72 in contact therewith. The conductive sleeve 72 also contacts a conductor 79 at a base of the bore 81.

The conductor 79 extends to the upper surface of the insulating element 73 near an outer periphery of the insulating element 73 where the conductor 79 is electrically connected to a flexible contact 83. The flexible contact 83 selectively engages a plurality of radial contacts 85 arranged on an upper inside surface of the housing 53. A weak spring 87 arranged around the splined section 71 engages a stop member 89 secured on the shaft 55 and the insulating element 73 to slightly bias the insulating element 73 towards the upper inside surface of the housing 53 to ensure contact between the flexible contact 83 and the upper inside surface of the housing 53. As best seen in FIG. 5, the radial contacts 85 on the upper inside surface of the housing 53 are arranged generally in the form of radial spokes extending from the center of the housing 53 with the number of contacts being equal to the number of cylinders 20 in the engine 21. The number of degrees covered by each of the radial contacts 85 gradually increases as the distance from the center of the upper inside surface of the housing 53 increases.

In operation of the device of FIGS. 4 and 5, as the shaft 55 rotates, electricity flows along a path through the wire 45 down through post 47 to the annular contact member 69 which is in constant contact with the spring biased contact 75. The electrical current passes through the conductive sleeve 72 to the conductor 79 and then to the flexible contact 83. As the flexible contact 83 rotates along with the insulating member 73 and the shaft 55, the tip of the flexible contact 83 successively engages each of the radial contacts 85 on the upper inside of the housing 53. As the speed of the shaft 55 increases, the insulating member 73 and the flexible contact 83 attached thereto move upwardly along the splined section 71 of the shaft 55 due to the radial component of the splines in the direction of rotation under the influence of centrifugal force. As the insulating member 73 moves upwardly, the flexible contact 83 is bent such that the tip of the contact 83 extends further radially outwardly from the center of the housing 53 (as seen in phantom lines in FIG. 4). In other words, the effective length of the flexible contact 83 increases as the speed of the engine 21 increases.

As the flexible contact 83 is bent and the tip of the contact 83 moves outwardly, the tip remains in contact with each of the radial contacts 85 for a longer period of each engine cycle due to the increased angular width of the radial contacts with increasing distance from the center of the housing 53. In this way, the length of time over which each of the valves 39 remains open is increased as the speed of the engine is increased. Thus, a larger quantity of compressed gas or air is injected into the cylinders as the speed increases. Conversely, as the speed decreases and the insulating member 73 moves downwardly along the splined section 71, a minimum quantity of air is injected into the cylinder due to the shorter length of the individual radial contact 85 which is in contact with the flexible contact 83. In this way, the amount of compressed gas that is used during idling of the engine 21 is at a minimum whereas the amount of compressed gas which is required to increase the speed of the engine 21 to a level suitable to drive a vehicle on a highway is readily available.

With reference to FIGS. 6 and 7, a third embodiment of a valve actuator 41 according to the present invention includes an arcuate insulating element 91 having a first end pivotally secured by any suitable device such as screw 92 to the shaft 55 for co-rotation with the shaft 55. The screw 92 is screwed into a tapped hole in the insulating element 91 such that a tab 94 at an end of the screw 92 engages a groove 96 provided in the shaft 55. In this way, the insulating element 91 positively rotates with the shaft 55. However, as the shaft 55 rotates faster, a second end 98 of the insulating element 91 is permitted to pivot outwardly under the influence of centrifugal force because of the groove 96 provided in the shaft 55. A spring 93 connected between the second end 98 of the element 91 and the shaft 55 urges the second end of the element 91 towards the center of the housing 53.

A contact 99 similar to the contact 59 (FIG. 2) is arranged such that one end of the contact 99 is in constant contact with the conducting plate 51 located centrally within the housing 53. The other end of the contact 99 engages a conductive sleeve 101 arranged in bore 102. A contact element 95 is arranged in the conductive sleeve 101 in constant contact with the sleeve 101. The bore 102 is arranged generally parallel to the shaft 55 near the second end of the arcuate insulating

element **91**. The contact **95** is biased by a spring **97** towards the upper inside surface of the housing **53** for selective contact with each of the plurality of radial contacts **85** which increase in arc length towards the outer peripheral surface of the housing **53** (FIG. **6**).

In operation of the device of FIGS. **6** and **7**, as the shaft **55** rotates the arcuate insulating element **91** rotates with the shaft **55** and the second end **98** of the insulating element **91** tends to pivot about the shaft **55** due to centrifugal force. Thus, as the effective length of the contact **95** increases, i.e., as the arcuate insulating element **91** pivots further outwardly, the number of degrees of rotation over which the contact **95** is in contact with each of the radial contacts **85** on the upper inside surface of the housing **53** increases thereby permitting each of the valves **39** to remain open for a longer period of each engine cycle to admit more compressed gas to the respective cylinder **20** to further increase the speed of the engine **21**.

With reference to FIG. **1**, a mechanical advance linkage **104** which is connected to the throttle linkage **35**, advances the initiation of the opening of each valve **39** such that compressed gas is injected into the respective cylinder further before the piston **22** in the respective cylinder **20** reaches a top dead center position as the speed of the engine is increased by moving the throttle linkage **35**. The advance linkage **104** is similar to a conventional standard mechanical advance employed on an internal combustion engine. In other words, the linkage **104** varies the relationship between the angular positions of a point on the shaft **55** and a point on the housing **53** containing the contacts. Alternatively, a conventional vacuum advance could also be employed. By advancing the timing of the opening of the valves **39**, the speed of the engine can more easily be increased.

The operation of the engine cycle according to the present invention will now be described. The compressed gas injected into each cylinder of the engine **21** drives the respective piston **22** downward to drive a conventional crankshaft (not shown). The movement of the piston downwardly causes the compressed gas to expand rapidly and cool. As the piston **22** begins to move upwardly in the cylinder **20** a suitable exhaust valve (not shown) arranged to close an exhaust passageway is opened by any suitable apparatus. The expanded gas is then expelled through the exhaust passageway. As the piston **22** again begins to move downwardly a suitable intake valve opens to admit ambient air to the cylinder. The intake valve closes and the ambient air is compressed on the subsequent upward movement of the piston until the piston reaches approximately the top dead center position at which time the compressed gas is again injected into the cylinder **20** to drive the piston **22** downward and the cycle begins anew.

In the case of adapting a conventional internal combustion engine for operation on compressed gas, a plurality of plates **103** are preferably arranged over an end of the exhaust passageways in order to reduce the outlet size of the exhaust passageways of the conventional internal combustion engine. In the illustrated embodiment, a single plate having an opening in the center is bolted to the outside exhaust passageway on each bank of the V-8 engine while another single plate having two openings therein is arranged with one opening over each of the interior exhaust passageways on each bank of the V-8 engine. A line **105** is suitably attached to each of the adaptor places to carry the exhaust to an appropriate location. In a preferred embodiment, the exhaust lines **105** are $1\frac{1}{2}''$ plastic tubing.

In a preferred embodiment, the exhaust lines **105** of one bank of the V-8 engine are collected in a line **107** and fed to an inlet of a compressor **109**. The pressure of the exhaust gas emmanating from the engine **21** according to the present invention is approximately 25 p.s.i. In this way, the compressor **109** does not have to pull the exhaust into the compressor since the gas exhausted from the engine **21** is at a positive pressure. The positive pressure of the incoming fluid increases the efficiency and reduces wear on the compressor **109**. The exhaust gas is compressed in the compressor **109** and returned through a line **111** and a check valve **113** to the compressed gas storage tank **23**. The check valve **113** prevents the flow of compressed gas stored in the tank **23** back towards the compressor **109**.

A suitable pressure sensor **115** is arranged at an upper end of the tank **23** and sends a signal along a line **117** when the pressure exceeds a predetermined level and when the pressure drops below a predetermined level. The line **117** controls an electrically actuated clutch **119** disposed at a front end of the compressor **109**. The clutch **119** is operative to engage and disengage the compressor **109** from a drive pulley **121**. Also, the signal carried by the line **117** actuates a suitable valve **123** arranged on a compressor housing **125** to exhaust the air entering the compressor housing **125** from the line **107** when the clutch **119** has disengaged the compressor **109** from the drive pully **121**.

In a preferred embodiment, when the pressure is the tank **23** reaches approximately 600 p.s.i., the clutch **119** is disengaged and the compressor **109** is deactivated and the valve **123** is opened to exhaust the expanded gas delivered to the compressor **109** from the line **107** to the atmosphere. When the pressure within the tank **23** drops below approximately 500 p.s.i., the sensor **115** sends a signal to engage the clutch **119** and close the valve **123**, thereby operating the compressor **109** for supplying the tank **23** with compressed gas.

The pulley **121** which drives the compressor **109** through the clutch **119** is driven by a belt **127** which is driven by a pulley **129** which operates through a gear box **131**. With reference to FIGS. **1** and **8**, a second pulley **133** on the gear box is driven by a belt **135** from a pulley **137** arranged on a drive shaft **139** of the engine **21**. The pulley **137** drives a splined shaft **140** which has a first gear **141** and a second larger gear **143** arranged thereon for rotation with the splined shaft **140**. The splined shaft **140** permits axial movement of the gears **141** and **143** along the shaft **140**.

In normal operation (as seen in FIG. **8**), the first gear **141** engages a third gear **145** arranged on a shaft **147** which drives the pulley **129**. The shafts **140** and **147** are arranged in suitable bearings **149** arranged at each end thereof. When the speed of the engine **21** drops below a predetermined level, a suitable sensor **151** responsive to the speed of the drive shaft **139** of the engine **21** generates a signal which is transmitted through a line **153** to a solenoid actuator **155** arranged within the gear box **131**. The solenoid actuator **155** moves the first and second gears **141**, **143** axially along the splined shaft **140** to the right as seen in FIG. **8** such that the second, larger gear **143** engages a fourth smaller gear **157** which is arranged on the shaft **147**. The ratio of the second gear **143** to the fourth gear **157** is preferably approximately 3 to 1.

In this way, when the speed of the engine **21** drops below the predetermined level as sensed by the sensor **151** (which predetermined level is insufficient to drive the compressor **109** at a speed sufficient to generate the 500–600 pounds of pressure which is preferably in the tank **23**), the solenoid actuator **155** is energized to slide the gears **143**, **141** axially along the splined shaft **140** so that the second, larger gear **143** engages the fourth, smaller gear **157** to drive the pulley **129** and hence the compressor **109** at a higher rate of speed to generate the desired pressure. When the speed of the engine increases above the predetermined level, in a preferred embodiment approximately 1500 rpm, the solenoid actuator **155** is deactivated by the sensor **151** thereby moving the gears **143** and **141** to the left as seen in FIG. **8** such that the first gear **141** re-engages with the third gear **145** to effectuate a 1 to 1 ratio between the output shaft **139** of the engine **21** and the pulley **129**.

The other bank of the V-8 engine has its exhaust ports arranged with adapter plates **103** similar to those on the first bank. However, the exhaust from this bank of the engine **21** is not collected and circulated through the compressor **109**. In a preferred embodiment, a portion of the exhaust is collected in a line **159** and fed to an enlarged chamber **161**. A second fluid is fed through a line **163** into the chamber **161** to be cooled by the cool exhaust emmanating from the engine **21** in the line **159**. The second fluid in the line **163** may be either transmission fluid contained in a transmission associated with the engine **21** or a portion of the oil used to lubricate the engine **21**. A second portion of the exhaust from the second bank of the V-8 engine is removed from the line **159** in a line **165** and used as a working fluid in an air conditioning system or for any other suitable use.

It should be noted that the particular arrangement utilized for collecting and distributing the gas exhausted from the engine **21** would be determined by the use for which the engine is employed. In other words, it may be advantageous to rearrange the exhaust tubing such that a larger or smaller percentage of the exhaust is routed through the compressor **109**. It should also be noted that since the exhaust lines **105** are plastic tubing, a rearrangement of the lines for a different purpose is both simple and inexpensive.

In operation of the engine of the present invention, the engine **21** is started by energizing the solenoid valve **29** and any suitable starting device (not shown), e.g., a conventional electric starter as used on an internal combustion engine. Compressed gas from the full tank **23** flows through the line **25** and a variable amount of the compressed gas is admitted to the distributor **33** by controlling the regulator valve **31** through the linkage **33** and the operator actuated throttle linkage **35**. The compressed gas is distributed to each of the lines **37** which lead to the individual cylinders **20**. The compressed gas is admitted to each of the cylinders **20** in timed relationship to the position of the pistons within the cylinders by opening the valves **39** with the valve actuator **41**.

When it is desired to increase the speed of the engine, the operator moves the throttle linkage **35** which simultaneously admits a larger quantity of compressed gas to the distributor **33** from the tank **23** by further opening the regulator valve **31**. The timing of the valve actuator **41** is also advanced through the linkage **104**. Still further, as the speed of the engine **21** increases, the effective length of the rotating contact **83** (FIG. 4) or **95** (FIG. 6) increases thereby electrically contacting a wider portion of one of the stationary radial contacts **85** to cause each of the valves **39** to remain open for a longer period of each engine cycle to admit a larger quantity of compressed gas to each of the cylinders **20**.

As can be seen, the combination of the regulating valve **31**, the mechanical advance **104**, and the valve actuator **41**, combine to produce a compressed gas engine which is quickly and efficiently adaptable to various operating speeds. However, all three of the controls need not be employed simultaneously. For example, the mechanical advance **104** could be utilized without the benefit of one of the varying valve actuators **41** but the high speed operation of the engine may not be as efficient. By increasing the duration of each engine cycle over which each of the valves **39** remains open to admit compressed gas to each of the cylinders **20** as the speed increases, conservation of compressed gas during low speed operation and efficient high speed operation are both possible.

After the compressed gas admitted to the cylinder **20** has forced the piston **22** downwardly within the cylinder to drive the shaft **139** of the engine, the piston **22** moves upwardly within the cylinder **20** and forces the expanded gas out through a suitable exhaust valve (not shown) through the adapter plate **103** (if employed) and into the exhaust line **105**. The cool exhaust can then be collected in any suitable arrangement to be compressed and returned to the tank **23** or used for any desired purpose including use as a working fluid in an air conditioning system or as a coolant for oil.

When using the apparatus and method of the present invention to adapt a ordinary internal combustion engine for operation with compressed gas it can be seen that considerable savings in weight are achieved. For example, the ordinary cooling system including a radiator, fan, hoses, etc. can be eliminated since the compressed gas is cooled as it expands in the cylinder. In addition, there are no explosions within the cylinder to generate heat. Further reductions in weight are obtained by employing plastic tubing for the lines which carry the compressed gas between the distributor and the cylinders and for the exhaust lines. Once again, heavy tubing is not required since there is little or no heat generated by the engine of the present invention. In addition, the noise generated by an engine according to the present invention is considerably less than that generated by an ordinary internal combustion engine since there are no explosions taking place within the cylinders.

The principles of preferred embodiments of the present invention have been described in the foregoing specification. However, the invention which is intended to be protected is not to be construed as limited to the particular embodiments disclosed. The embodiments are to be regarded as illustrative rather than restrictive. Variations and changes may be made by others without departing from the spirit of the invention. Accordingly, it is expressly intended that all such variations and changes which fall within the spirit and the scope of the present invention as defined in the appended claims be embraced thereby.

What is claimed is:

1. An apparatus for operating an engine having at least one cylinder and a reciprocating piston therein comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder;

altering means for increasing the duration of each engine cycle over which the valve means admits compressed gas to the at least one cylinder as the speed of the engine increases; and

exhaust means for exhausting gas as the piston subsequently approaches approximately the top dead center position.

2. The apparatus of claim **1** further comprising control means for controlling the amount of compressed gas admitted to the distributor means.

3. The apparatus of claim **1** wherein the valve means is a solenoid valve secured in an opening in the cylinder above the level of the piston at the top dead center position.

4. The apparatus of claims **1** or **2** further comprising means for advancing the timing of the valve means as the speed of the engine increases such that compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

5. The apparatus of claim **4** wherein the means for advancing the timing comprises a mechanical linkage connected to an operator actuated accelerator linkage.

6. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is compressed in a compressor driven by an output shaft of the engine and is returned to the source of compressed gas.

7. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is used to cool transmission fluid for a transmission associated with the engine.

8. The apparatus of claim **1** wherein a portion of the gas exhausted through the exhaust means is used as a working fluid in an air conditioning system.

9. The apparatus of claim **6** further comprising first gearing means interposed between the output shaft of the engine and the compressor for increasing the speed at which the compressor is driven.

10. The apparatus of claim **6** further comprising clutch means attached to the compressor both for disengaging the compressor from the output shaft of the engine when a first predetermined pressure at the source of compressed gas is exceeded and for engaging the compressor with the output shaft of the engine when the pressure at the source of compressed gas drops below a second predetermined pressure.

11. The apparatus of claim **9** further comprising means for both disengaging the first gearing means when a predetermined speed of the engine is exceeded and engaging a second gearing means for driving the compressor at a speed slower than the first gearing means when the predetermined speed of the engine is exceeded.

12. The apparatus of claim **1** wherein the valve means is electrically actuated and wherein the altering means comprises:

a rotating member timed with the at least one cylinder and arranged within a housing;

first and second contacts arranged on a first end of the rotating member and on an inside surface of the housing, respectively;

means for increasing the distance of the first contact from the rotational axis of the rotating member as the speed of the engine increases such that the first contact moves radially outwardly within the housing; and

said second contact presenting a longer arc length to the first contact as the distance of the first contact from the rotational axis of the rotating member increases.

13. The apparatus of claim **12** wherein the rotating member comprises an arcuate arm and wherein the means for increasing the distance of the first contact comprises pivotally mounting a second end of the arcuate arm about the axis of rotation of the rotating member and spring means for biasing the first end of the arcuate arm towards a radially inward position whereby the first end of the arcuate arm pivots radially outwardly as the speed of the engine increases.

14. The apparatus of claim **12** wherein the rotating member is axially slidably received on a rotating shaft for co-rotation therewith, said shaft having splines with a radial component in the direction of rotation, and wherein the first contact comprises a flexible contact located on an upper surface of the rotating member, said flexible contact being biased against the inside surface of the housing which carries the second contacts whereby as the speed of the engine increases the rotating member is urged axially along the splined shaft towards the inside surface of the housing such that the flexible contact is forced radially outwardly along the inside surface.

15. The apparatus of claim **12** wherein the second contact comprises of radially extending conductor arranged on an upper inside surface of the housing, said conductor increasing in arc length as the conductor extends radially outwardly from a central portion of the housing.

16. An apparatus for adapting an internal combustion engine for operation with compressed gas, the internal combustion engine having at least one cylinder, a piston reciprocable within the at least one cylinder, intake and exhaust means disposed in the at least one cylinder, and a tapped hole in the at least one cylinder adapted to receive a spark plug, the apparatus comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means arranged in the tapped hole for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder; and

altering means for increasing the duration of each engine cycle over which the valve means remains open to admit the compressed gas as the speed of the engine increases.

17. An apparatus as in claim **16** further comprising first adapter plate means for supporting the distributor means above an intake manifold of the engine, which adaptor plate means allows ambient air to enter through the intake manifold.

18. The apparatus of claim **16** further comprising second adapter plate means for reducing the exit area of the exhaust means.

19. A method of operating an engine on compressed gas, said engine having at least one cylinder and a piston reciprocable therein comprising the steps of:

delivering compressed gas from a source to a distributor;

distributing the compressed gas to the at least one cylinder;

admitting compressed gas to the at least one cylinder through an intake valve when the piston is at approximately a top dad center position;

increasing the duration of each engine cycle over which compressed gas is admitted to the at least one cylinder as the engine speed increases; and

exhausting the remaining gas when the piston subsequently reaches approximately the top dead center position.

20. The method of claim **19** further comprising the step of controlling the amount of compressed gas which is delivered to the distributor.

21. The method of claim **19** further comprising the step of advancing the timing of the opening of the intake valve as the speed of the engine increases.

22. An apparatus for operating an engine having at least one cylinder and a piston reciprocable therein on compressed gas comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

electrically actuated valve means secured in an opening in the at least one cylinder for selectively admitting compressed gas to the at least one cylinder when the piston is in approximately a top dead center position; and

means for advancing the timing of the valve means as the speed of the engine increases whereby compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

[57] **ABSTRACT**

A supercharger for delivering supercharged air to an engine, comprising a shrouded axial compressor, a radial compressor which is located downstream of the axial compressor and a housing. The housing comprising four sections, including a section defining a highly convergent, frustoconical transition duct which favorably directs the discharge of the axial compressor to the inlet of the radial compressor and a hollow, highly convergent, exhaust cone section immediately downstream of the radial compressor which converges into the exhaust port of the supercharger. An annular flow deflector is provided for directing the discharge of the radial compressor into the exhaust cone.

SUPERCHARGER FOR AUTOMOBILE ENGINES

FIELD OF THE INVENTION

The present invention relates to superchargers generally and more particularly to superchargers for automotive engines which include both an axial stage compressor and a centrifugal stage compressor.

BACKGROUND OF THE INVENTION

Superchargers impart additional pressure to the air or the air/fuel mixture of an engine so that the cylinders receive a greater weight per unit volume of air or air/fuel mixture than would otherwise be supplied. As a result, the volumetric efficiency and power output of the engine are improved.

According to prior practices, superchargers generally comprise a single airblower which forces air on an air/fuel mixture into the cylinders of an engine. Typically, the airblower is driven by a gear train which is connected to the crankshaft of the engine with a gear ratio of about 6 to 1. These prior types of superchargers have been used extensively in racing engines and radial aircraft engines. However, by reason of their high operating speeds and their gear trains, these superchargers have been considered too complicated, too heavy and too costly for use with mass production engines such as are found in automobiles and trucks.

Recently, some automobile manufacturers have been offering turbocharged engines which expand to exhaust gases of the engine through a turbine to drive a centrifugal compressor. Although turbochargers are advantageous in that the turbine can deliver large amounts of power to the compressor, their extreme operating speeds require special bearings, lubrication and maintenance. In addition, turbochargers require special ducting, such as by-pass arrangements, which only add to their cost and maintenance requirements. Consequently, turbochargers are only offered as expensive options in automobiles.

Further, there is current interest in a new type of automobile engine which operates from tanks of compressed gas to effect reciprocation of its pistons. An example of such an engine can be found in the U.S. Pat. No. 4,292,804 issued to the same inventor of the present invention. In the referenced patent, at least a portion of the partially expanded exhaust gas from the cylinders is directed to a compressor where it is recompressed and then returned to the storage tanks from whence it originally came. It would be desirable that at least some, if not all of the aforementioned recompression of the exhaust gas could be achieved with a belt-driven, rotary supercharger that is easily manufactured and maintained, yet is capable of providing ample recompression.

OBJECTS OF THE INVENTION

Accordingly, an object of the present invention is to provide a supercharger suitable for improving the performance of engines of automobiles, helicoptors or the like, which supercharger is inexpensive to produce and easy to maintain.

It is another object of the present invention to provide a supercharger which provides sufficient boost without resort to extreme operating speeds and accordingly avoids the costly complications associated with high speed operation.

It is yet another object of the present invention to provide a relatively compact and lightweight supercharger which is inexpensive to manufacture and maintain.

Another object of the present invention is to provide a belt-driven supercharger having a design which provides supercharging compression at relatively low operating speeds.

It is still another object of the present invention to provide a supercharger which can be quite readily disassembled and reassembled for purposes of low cost maintenance and repair.

Still another object of the present invention is to provide a supercharger which can be constructed from mass productible parts to thereby reduce the cost of its manufacture.

It is still another object of the present invention to provide a belt-driven supercharger which provides supercharging compression without resort to a larger number of compressor stages.

Yet another object of the present invention is to provide a rotary supercharger for a gas operated engine, which supercharger is easily manufactured and maintained, yet capable of providing ample recompression of the recirculating drive fluid.

SUMMARY OF THE INVENTION

These and other objects are achieved by the present invention which provides a supercharger comprising a housing having an inlet and an outlet, a shrouded axial compressor and a radial compressor rotatably mounted within the housing, a highly convergent shallow, frustoconical transition duct for favorably directing the discharge of the axial compressor to the inlet of the radial compressor.

In accordance with a further aspect of the invention, the above-described supercharger further comprises an exhaust cone at a location downstream of the radial compressor and a flow deflector for directing the discharge of the radial compressor to the exhaust cone.

In the preferred embodiment, the housing itself comprises four sections: a cylindrical front housing section which defines an axially directed inlet; a second, cylindrical ducting section enclosing the axial compressor; a rear housing section defining the transition duct as well as the inlet and casing for the radial compressor; and the exhaust cone section which defines at its terminis the outlet of the housing. For driving the compressor shaft, a double-tracked pulley wheel is secured to the forward end of the common shaft, which pulley wheel is adapted to receive one or more drive belts from the crank-shaft wheel of the engine. A lateral opening in the front housing section accommodates the connection with the drive belts.

With the disclosed arrangement, compression can be achieved for supercharging purposes without resort to a large number of compressor stages or high operating speeds. Additionally, the design of the disclosed supercharger avoids the need for guide vanes between the axial compressor and the radial compressor. The exhaust cone section also favorably avoids the build-up of back pressure against the radial compressor. The design is also very simple and therefore inexpensive to manufacture and maintain.

Other objects, advantages and novel features of the present invention will become apparent from the following detailed description of the invention when considered in conjunction with the accompanying drawing.

BRIEF DESCRIPTION OF THE DRAWINGS

A preferred embodiment of the present invention is described in greater detail with reference to the accompanying drawing wherein like elements bear like reference numerals, and wherein:

FIG. 1 is a cross-sectional side view of a supercharger constructed in accordance with the preferred embodiment of the present invention;

FIG. 2 is a side view of the supercharger of FIG. 1;

FIG. 3 is a frontal view of the impeller of the supercharger of FIG. 1;

FIG. 4 is a cross-sectional view taken along line 4—4 of FIG. 1;

FIG. 5 is a cross-sectional view taken along line 5—5 in FIG. 1;

FIG. 6 is a cross-sectional view taken along line 6—6 in FIG. 1;

FIG. 7 is a perspective view of a segment of the impeller of the supercharger of FIG. 1; and

FIG. 8 is a partial side view of the supercharger of FIG. 1 with an adaptor.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to FIGS. **1** and **2**, a supercharger **10** is provided for supplying supercharged air to an automobile engine or the like, so that the engine receives a greater weight per unit volume of air or a fuel/air mixture than would be otherwise supplied. In accordance with a preferred embodiment of the present invention, the supercharger **10** comprises a housing **12** having an axially directed inlet **14** for receiving ambient air and an axially directed outlet **16** for delivering supercharged air to the intake of the automobile engine. Rotatably mounted within the housing **12** is a shaft **18** on which are secured an axial compressor **24** and a radial compressor **26**, the radial compressor **26** being positioned downstream of the axial compressor **24**. A pulley wheel **28** is secured to a forward end **30** of the shaft for receiving drive belts **31**, which belts drivingly connect the shaft **18** to a pulley wheel on the crankshaft of the engine (not shown). The drive belts **31** deliver torque to the shaft **18** as required for driving the compressors **24** and **26** of the supercharger **10**.

The housing **12** itself is constructed from four sections which are preferably bolted together at flanged connections in end-to-end relationship. These sections include a front housing section **32**, an axial compressor duct section **34**, a rear housing section **36** and an exhaust cone section **38**. The shaft **18** extends along the longitudinal axis of the housing **12**.

The front housing section **32** is a hollow cylinder which extends forward of a front bearing support **40**. The front housing section **32** encloses the forward end **30** of the shaft **18** and the associated pulley wheel **28**. At its forward end, the front housing section **32** defines the inlet **14** for receiving air from an external source (not shown). Referring particularly to FIG. **2**, the front housing section **32** includes a lateral opening **44** on one side in order to accommodate the connection of the drive belts **31** to the pulley wheel **28**. The front housing section **32** also includes a forward flange **46** for accommodating the connection of air filters, carburetors, air scoops or the like upstream of the supercharger **10** according to the particular engine layout.

It is to be understood that in the usual engine layout, the supercharger **10** receives air or a fuel/air mixture from an external source through its inlet **14**, compresses the air or fuel/air mixture and then delivers it to the intake of the engine.

Referring again to FIG. **1**, the pulley wheel **28** is interference-fitted upon the forward end **30** of shaft **18** and a key **134** is used to lock the pulley wheel **28** in place. The pulley wheel **28** is preferably a double-track design which is suitable for the attachment of twin drive belts, although a single-belt type pulley wheel would be adequate. The pulley wheel **28** is preferably sized such that the ratio of its diameter with respect to the diameter of the drive wheel of the engine's crankshaft provides an effective gearing ratio in the range of approximately two and one-half to four and one-half. Thusly at idle, when the automobile engine is running approximately 700 rpm, the supercharge **10** is running at approximately 2,400 rpm, and at cruise, when the engine is running in the range of 2,500, the supercharger **10** is preferably turning over in the range of 6,000 to 8,000 rpm. It is to be noted that although the diameter of the pulley wheel **28** may be substantially reduced in order to achieve a desired gearing ratio, the double-track wheel **28** presents a sufficient sum total of surface area to avoid slippage of the belts **31**.

The next adjacent section of housing **12** is the axial compressor duct **34** comprising a short cylinder which is coaxially disposed about the axial compressor **24**. Preferably, the axial compressor duct **34** is constructed from cast aluminum, with the interior surfaces **48** machined to assure uniform clearance between the duct **34** and a shroud **50** of the axial compressor **24**. As with other sections of the housing **12**, the axial compressor duct **34** is provided with flanges **52** and **54** for effecting connection to the adjacent housing sections. The axial compressor duct **34** guides air delivered from the front housing section **32** toward the axial compressor **24**.

Referring now to FIGS. **1** and **4**, a front bearing support **40** is interposed between the front housing section **32** and the axial compressor duct **34**. The front bearing support **40** includes an outer annulus **56** and three radially directed arms **58** between which arms are defined passages **60** for allowing air to pass through the bearing support **40**. The outer annulus **54** is secured by bolts connecting a rear flange **64** of the front housing section **32** and the flange **52** of the axial compressor duct **34**. By such arrangement, the front bearing support **40** is rigidly secured to the housing **12** such that loads and shocks to the shaft **18** can be transferred through the front bearing support **40** to the housing **12**.

In the preferred embodiment, the outer annulus **56** of the bearing support **40** extends into the region of the inlet **14** of the front housing section **32** such that its inner rim **68** coincides with the inner rim **70** of the shroud **50** of the axial compressor **24**. In this fashion the outer annulus **56** contributes to the guiding of the flow of air toward the axial compressor **24**.

An outer raceway **74** of the front roller bearing assembly **76** is secured between the front bearing support **40** and a bearing retainer plate **78**, which plate **78** is secured by removable bolts **80**. In the preferred embodiment, the front bearing assembly **76** is of the sealed, high speed type. A suitable commercially available bearing assembly is marketed under model Fafnir 405KDD. A lower raceway **82** of the front bearing assembly **76** is preferably secured to the shaft **18** with an interference fit. A spacer **84** is provided on one side of the lower raceway **82**, which spacer **84** also abuts a hub **86** of the axial compressor **24** to thereby place the axial compressor **24** a predetermined distance downstream of the bearing support **40**. Similarly, a spacer **88** is provided on the other side of the lower raceway **84**, which spacer **88** also abuts the pulley wheel **28** so as to space apart the pulley wheel **28** from the front bearing support **40** to assure sufficient clearance between same.

It is to be appreciated that the bearing retainer plate **78** allows ready access to the front bearing assembly **76** for purposes of maintenance or repair. To service the front bearing assembly **76**, a nut **90** and lock-washer **92** on the forward end **30** of the shaft **18** are loosened and removed together with the pulley wheel **28** and the spacer **88**. Then bolts **42** and the bearing retainer plate **76** are removed, leaving the whole bearing assembly **76** exposed for servicing and/or removal.

The rear housing section **36** is connected by bolts to the downstream end of the axial compressor duct **34**. Preferably, the rear housing section **36** is constructed from a single section of cast aluminum and includes external longitudinal ribs **94** for enhancing the structural rigidity of the rear housing section **34**. The walls of the rear housing section **36** define three elements of the supercharger **10**: a highly conical transition duct **96** which favorably directs the output of the axial compressor to an inlet **98** of the radial compressor **26**; the inlet **98** of the radial compressor **26**, itself; and a casing **100** for the radial compressor **26**.

The transition duct **96** is a hollow, frustoconical portion having a half-apex angle (from the generatrix to the axis of symmetry) of approximately 35°. The angle is selected such that the inlet to the radial compressor **26** is as close as possible to the outlet of the axial compressor **24** without causing undue back-pressure. In the preferred embodiment, the transition duct **96** begins a short distance downstream of the axial compressor **24** and ends at the beginning of the inlet **98** of the radial compressor **26**. The highly conical shape of the transition duct **96** is believed to roll-in the higher volume of air being discharged from the more radially outward portions of the axial compressor **24**. This rolling-in action is believed to promote a favorable flow regime at the inlet **98** of the radial compressor **26** such that the need for inlet guide vanes for the radial compressor **26** is avoided. It is also believed that the highly conical shape of the transition duct **96** affects upstream flow conditions at the axial compressor **24** such that its performance is improved. It has also been found that the need for a stator (or exit guide vane) for the axial compressor **24** is likewise avoided.

In essence, it is believed that the transition duct **96** performs the functions of the aforementioned exit vanes of axial compressors and inlet guide vanes of radial compressors, but without the pressure losses commonly associated with them. Because of the avoidance of these pressure losses and by reason of the expected improvement in the performance of the axial compressor, the supercharger **10** is able to impart a higher overall pressure ratio than would otherwise be achieved without the transition duct **96**. As a result, adequate compression is achieved at moderate operating speeds without resort to a bank of several axial compressors. It is to be understood, however, that when connecting the supercharger **10** to a relatively slowly recziprating diesel or a very large engine, it may be desirable to include two or more axial compressors in order to boost the supercharger's overall pressure ratio. In such case, practice of the present invention would include the placement of a transition duct as above described downstream of at least the last axial compressor.

At the inlet **98** of the radial compressor **26**, the walls of the rear housing **36** are cylindrical and coaxially disposed about the shaft **18**. It is to be noted that in the preferred embodiment, the surface transition **102** from the transition duct **96** to the inlet **98** is rounded-off.

The casing portion **100** of the rear housing section **36** closely follows the contour defined by blade edges **104** of the radial compressor **26** in a close, substantially sealing manner as is well known in the art of radial compressors. The casing portion **100** of the rear housing section **78** channels air between the rotating blades of the radial compressor **26** so that the blades can impart work to the passing air. The casing portion **100** also defines a discharge outlet **106** for the radial compressor **26**.

Just beyond the discharge outlet **106** of the radial compressor **26**, the interior surfaces of the rear housing section **36** begin to curve immediately inwardly to provide a transition into the next adjacent section of the housing **12**, the exhaust cone **38**. In this fashion, the interior surfaces at the rear-most portion of rear housing section **36** and those of the forward portion of the exhaust cone **92** define internally a flow deflector **108**. In the preferred embodiment, the flow deflector **108** is closely and concentrically disposed about the outlet **106** of the radial compressor **26** such that the air being discharged from the radial compressor **26** does not have the opportunity to diffuse significantly prior to its arrival at the annular flow deflector **108**. The annular flow deflector **108** directs the output of the radial compressor **26** into the exhaust cone **38** by providing a smooth surface transition from the interior of rear housing section **36** to the interior of the exhaust cone **38**.

The exhaust cone **38** is a highly convergent, hollow, frustoconical section placed immediately downstream of the radial compressor **26** for receiving the output of the radial compressor **26** from the annular flow deflector **108**. In the preferred embodiment, the exhaust cone **38** is a single section of cast aluminum which is joined to the downstream end of the rear housing section **36** at a flanged joint **110**. Preferably, the exhaust cone **92** converges according to a half-apex angle of approximately 35° and defines the exhaust port **16** at its terminus. Threading **112** at the exhaust port **16** accommodates the attachment of the appropriate external ducting (not shown) leading to the intake of the engine.

During operation of the supercharger **10**, the space enclosed by the exhaust cone **92** prevents the build up of an elevated back pressure which might otherwise arise and detract from the operation and efficiency of the radial compressor **26**. The enclosed space of the exhaust cone **92** is also of sufficient volume to absorb pulses and to average out unsteady flow conditions so to promote a smooth and continuous output from the supercharger **10**.

Referring now to FIGS. **1** and **6**, the exhaust cone **38** includes a rear bearing support **114** which comprises members **116** which extend radially inwardly from the outer walls of the exhaust cone **38**. At a radial inward location close to the shaft **18**, the members **116** converge to form a cupped annulus which serves as a housing **118** for the rear bearing assembly **120**. The housing **118** is open towards the rear face of the radial compressor **24** to facilitate disassembly of the supercharger **10**. The rear bearing assembly **120** is the same type and size as the front bearing assembly **76**. The inner race **122** of the bearing assembly **120** is set in place on the shaft **18** by spacers **124** and **126** in conjunction with a nut **128** and washer **130** on the rearward end **132** of the shaft **18**. In the preferred embodiment, the members **116** are integrally formed with the walls of the exhaust cone **38**.

Referring to FIGS. **1** and **5**, the axial compressor **24** upon rotation draws air through the inlet **14** and imparts an initial amount compression to the air as it forces the air into the transition duct **96** of the rear housing section **36**. In the preferred embodiment, the axial compressor **24** comprises a hub **86**, the shroud **50** and a series of ten (10) equally spaced, radially disposed blades **136**. Preferably, each blade **136** increases in cord from a root **138** to a tip **140** and includes a trailing edge **142** and a leading edge **144**, which edges are both slightly curved. The blades gradually increase in pitch from approximately 12° at the root **138** to approximately 36° at the tips **140**. However, the particular values of pitch and other geometrical aspects of the blades **136** might be varied in accordance with different operating speeds or other parameters as would be apparent to one skilled in the pertinent art and familiar with this disclosure.

The axial compressor **24** is preferably constructed from a single, cast aluminum section with the faces **143** and **145** of the hub **86** being machined for purposes of achieving accurate, axial positioning of the axial compressor **24** on the shaft **18** relative to the housing **12**. The faces **146** and **148** of the shroud **72** are also machined flat. Additionally, the outer periphery **150** of the shroud is machined to assure uniform clearance between the shroud and the adjacent interior surfaces **48** of the axial compressor duct **34**. The axial compressor **24** is preferably secured to the shaft **18** by an interference-fit onto a stepped portion **152** of the shaft **18**. The spacers **84** and **154** axially position the axial compressor **24** relative to the front bearing support **40** and the radial compressor **26**, respectively.

Dynamic balance test machines of the conventional type may be used to test the balance of the axial compressor **24** prior to its installation. If an imbalance is detected, material can be removed at the outer periphery **150** of the shroud **50** so as to achieve proper balance.

Referring now to FIGS. **1**, **3**, and **7**, the radial compressor **26** is constructed from a single section of cast aluminum and includes a hub **156** and curved blades **158**. Interposed between each pair of blades **158** are a second set of blades **160** which terminate short of the intake **162** of the radial compressor **26** so that the intake **162** is not crowded by both sets of blades. Accordingly, the radial compressor **26** features both a large total number of blades and an intake of relatively small diameter, which features enhance the performance of the compressor **26**. In the region of the intake **162**, the blades **158** present leading edges **164** and undergo a twist into the direction of rotation so as to prevent a favorable angle of attack at the intake **162**.

Preferably, the radial compressor **26** is positioned upon the stepped section **128** of the shaft **18** with an interference-fit and locked against rotational slippage by a key **166**. The spacer **124** assures clearance between the rear face of the radial compressor **26** and the rear bearing assembly **120**.

The shaft **18** is constructed from a hardened steel and is threaded at both ends **30** and **132** for receiving nuts **90** and **128**, respectively. In addition to the central stepped portion **152**, which receives the compressors **24** and **26**, the shaft **18** also features stepped portions **170** and **172** for receiving the front and rear bearing assemblies **76** and **120**, respectively. The stepped arrangement of the shaft **18** facilitates assembly and disassembly in that the stepped portion **152** of the greatest diameter is centrally located on the shaft **18** and all the stepped portions are greater than the diameter of the threading at ends **30** and **132**.

It is to be noted that the bearing supports **40** and **114** are in a fixed position relative to the housing **12** and that the compressors **24** and **26** are positioned between the bearing supports **22** and **40** by spacers **84**, **124** and **154**, which spacers have predetermined lengths. Consequently, the placement of the compressors **24** and **26** relative to the longitudinal axis of the housing **12** is fixed by the aforementioned spacers and not by the axial location of the shaft **18** relative to the housing **12**. It is also to be noted that the stepped portions **152**, **170** and **172** of the shaft **18** are each provided with extra lengths such that the respective components (the bearing assemblies and compressors) can each be situated over a relatively wide range of situses in the respective stepped portions. Thusly, the shaft **18** need not be accurately positioned along the longitudinal axis of the housing **12** in order to achieve proper assembly of the supercharger **10**. For instance, if nuts **90** and **128** had been tightened differently than as they appear in FIG. **1**, the shaft **18** might have been displaced slightly in the axial direction from where it is shown in FIG. **1**. However, the relative positioning of the various components on the shaft **18**, i.e., the pulley wheel **28**, the compressors **24** and **26** and the bearing assemblies **76** and **120**, would have remained the same relative to themselves and the housing **12**. This feature eases the process of manufacture and accordingly, reduces the costs of same. It also reduces the amount of labor required for reassembly after repair.

In operation, the supercharger **10** is suitably connected at its outlet **16** to an intake of an automobile engine, with the drive belts **31** from the crankshaft of the engine being attached to the pulley wheel **28** of the supercharger **10**. Then, as the engine is operated, torque is transferred by the drive belts **31** to the pulley wheel **28** for driving the compressors **24** and **26**. Upon rotation, the axial compressor **24** draws air through the inlet **14**, imparts an initial amount of compression to the air and discharges it into the transition duct **96** with a swirl. By reason of its design, the axial compressor **24** is believed to move a greater volume of air in the region of its blade tips **140** than at its more radially inward locations. Accordingly, there is a greater of mass of air situated at the outer annular region behind the axial compressor **24** than at the inner annular region. As the discharge from the axial compressor **24** is caused to leave the axial compressor duct **34**, the highly convergent, transition duct **96** is believed to cause the outer annulus of air which is discharged from the axial compressor **24** to roll-in. This action is believed to have two favorable results. First, the roll-in action causes a flow regime to be established at the inlet **98** of the radial compressor **26** such that the need for a guide vane is wholly avoided. Secondly, and of equal importance, the rolling-in action, in conjunction with the large volume of space enclosed by the transition duct **96**, is believed to favorably effect the performance of the axial compressor **24** such that a higher pressure ratio is obtained therefrom.

Since the overall pressure ratio of the supercharger **10** is the product of the pressure ratios of the two compressors, it can be seen that the aforementioned increase in performance of the axial compressor **24** results in a corresponding improvement in overall performance of the supercharger **10**. It is also to be noted that the deletion of inlet guide vanes for the radial compressor **26** and of exit vanes for the axial compressor **24** greatly simplifies the design of the rear housing section **36** and therefore provides savings in costs of manufacture. It also avoids the pressure losses associated with such guide vanes, which are often quite significant.

Upon leaving the transition duct **96**, the pre-swirled flow of air enters the inlet **98** of the radial compressor **26** and then into the compressor **26** itself. In passing through the radial compressor **26**, the air is turned and whirled such that the airflow is centrifugally discharged with a substantial radial velocity component, whereupon the resultant flow is abruptly turned by the annular flow deflector **108** and caused to enter the exhaust cone **38**. As previously explained, the large volume of space enclosed by the exhaust cone **38** induces flow conditions behind the radial compressor **26** such that elevated back pressures are avoided which might otherwise impair the performance of the radial compressor **26**. Pulses in the output of the radial compressor **26** are also moderated. The air is then delivered in a compressed state to the exhaust port **16** of the exhaust cone **38**. The supercharged air then flows down the appropriate intake system of the engine until it reaches the cylinder or cylinders of the engine.

With respect to the application of the supercharger **10** to air-tank powered engines, such as disclosed in U.S. Pat. No. 4,292,804, the supercharger **10** functions in the same manner as described above, but is connected to the engine differently. In the air tank powered engine, at least one of the exhaust manifolds of the engines delivers partially expanded air to a line connected to the inlet **14** of the supercharger **10**. Referring to FIG. **8**, in most of such applications, this line will be of a smaller diameter than the housing **12** at the inlet **14** of the supercharger **10**, such that an adaptor **173** is needed. The adaptor **173** comprises an annular plate **174** having a threaded aperture **176** sized to receive a mating, threaded end **178** of the aforementioned line **180**. The plate **174** is secured the flange **36** of the front housing section **32** by a plurality of bolts. Because the air coming from the line **180** is usually less than the full capacity of the supercharger, additional air is introduced through the lateral opening **44** along the side of the front housing section **32**. In this application, the opening **44** thusly serves as an air intake port as well as a means for accommodating the drive belts **31** and must therefore be sized upon the additional criteria that it not be so large as to upset the flow of the incoming air in the line **180**. Upon the passage of the air through the supercharger, the air is directed through the exhaust port **16** and into a suitable line connected thereto, which line may lead directly to the engine or to the storage tanks of the engine. If directed to the tanks, this recompressed air is utilized to supplement the required recharging of the storage tanks.

It is to be appreciated that savings in the cost of manufacturing the supercharger **10** are achieved by reason that the housing **12**, the bearing supports **40** and **114**, the axial compressor **24** and the radial compressor **26** are all constructed from cast aluminum parts and require only a minimum amount of machining. Moreover, the roller bearing assemblies **76** and **120** are commercially available components, and the supercharger **10** is easily assembled. These aspects further reduce the cost of manufacture and render the disclosed supercharger inexpensive to maintain and overhaul. More importantly, the supercharger **10**, despite its simple design, provides supercharging at relatively low operating speeds. With its lower operating speeds, the service life of the supercharger **10** is extended and the risk of it suffering mechanical failure is reduced. The need for special bearing designs and lubrication is also avoided. Accordingly, the supercharger **10** is highly suitable for mass production and for use in automobiles, trucks, helicoptors or the like.

It is to be understood that the present invention may be embodied in other specific forms without departing from the spirit or essential characteristics of the present invention. The preferred embodiments are therefore to be considered illustrative and not restrictive. The scope of the invention is set forth in the appended claims rather than by the foregoing descriptions and all changes or variations which fall within the meaning and range of the claims are therefore intended to be embraced therein.

What is claimed is:

1. A supercharger comprising:

a housing having a longitudinal axis and being constructed from sections, which sections are connected in end-to-end relationship with flanged joints, said sections including a front housing section defining an axially directed inlet, an axial compressor duct section for housing an axial compressor, a rear housing section downstream of said axial compressor duct section, and a hollow, highly convergent, frustoconical, exhaust cone section downstream of said rear housing section, a downstream portion of said rear housing section defining a cylindrical, axially directed inlet for a radial compressor, a casing for a radial compressor, and a substantially radially directed outlet for a radial compressor, said rear housing section further defining a highly convergent, hollow, frustoconical transition duct between a downstream end of said axial compressor duct section and said radial compressor inlet, said rear housing section having interior surfaces for defining a flow deflector, which flow deflector receives the output of said outlet for a radial compressor, which flow deflector provides a smooth surface transition from said rear housing section into said exhaust cone section, said exhaust cone section defining at a downstream end a coaxial outlet, said housing further including at least two bearing supports affixable within said housing according to predetermined locations along said longitudinal axis of the housing, said bearing mounts rotatably supporting a compressor shaft, which compressor shaft is positioned along said longitudinal axis;

sealed bearing assemblies removably implaced in said bearing supports, said sealed bearing assemblies receiving said compressor shaft;

a shrouded axial compressor located within said axial compressor duct and secured to said shaft to be rotatable therewith, said shrouded axial compressor drawing a flow from said inlet of the front housing section and imparting an initial compression to said flow;

a radial compressor located within said casing and secured to said shaft to be rotatable therewith, said casing being in a substantially sealing relationship with said radial compressor, said radial compressor including a hub, a first set of blades extending radially from said hub and having leading edges at an intake region of said radial compressor and a second set of blades extending radially from said hub and having leading edges downstream of said intake region, said radial compressor further compressing said flow;

at least one pulley wheel secured to said compressor shaft and adapted to receive drive belts;

spacers fitted upon said compressor shaft for axially positioning said axial compressor and said radial compressor relative to each other and relative to said bearing supports; and

means for securing said compressor shaft against axial displacement;

wherein said transition duct favorably directs the output of the axial compressor into said inlet of the radial compressor and said exhaust cone section encloses sufficient volume to moderate the output of said radial compressor.

2. The supercharger as claimed in claim **1** wherein said transition duct section and said exhaust cone section each have a half-apex angle of approximately 35°.

3. A supercharger comprising:

a housing having a longitudinal axis and being constructed from sections, which sections are connected in end-to-end relationship, said sections including a front housing section defining an axially directed inlet, an axial compressor duct section for housing an axial compressor, a rear housing section downstream of said axial compressor duct section and an exhaust section having a hollow, highly convergent, frustoconical, exhaust cone portion downstream of said rear housing section, a downstream portion of said rear housing section defining a cylindrical, axially directed inlet for a radial compressor, a casing for a radial compressor, and a substantially radially directed outlet for a radial compressor, said rear housing section further defining a highly convergent, hollow, frustoconical transition duct between a downstream end of said axial compressor duct section and said radial compressor inlet, said rear housing section having interior surfaces for defining a flow deflector, which flow deflector receives the output of said outlet for a radial compressor, which flow deflector provides a smooth surface transition from said rear housing section into said exhaust section, said exhaust cone portion defining at a downstream end a coaxial outlet, said housing further including at least two bearing supports affixable within said housing according to predetermined locations along said longitudinal axis of the housing, said bearing mounts rotatably supporting a compressor shaft, which compressor shaft is positioned along said longitudinal axis;

bearing assemblies removably implaced in said bearing supports, said bearing assemblies receiving said compressor shaft;

an axial compressor located within said axial compressor duct and secured to said shaft to be rotatable therewith, said axial compressor drawing a flow from said inlet of the front housing section and imparting an initial compression to said flow;

a radial compressor located within said casing and secured to said shaft to be rotatable therewith, said casing being in a substantially sealing relationship with said radial compressor, said radial compressor including a hub, a first set of blades extending radially from said hub and having leading edges at an intake region of said radial compressor and a second set of blades extending radially from said hub and having leading edges downstream of said intake region, said radial compressor further compressing said flow;

at least one pulley wheel secured to said compressor shaft and adapted to receive drive belts;

spacers fitted upon said compressor shaft for axially positioning said axial compressor and said radial compressor relative to each other; and

means for securing said compressor shaft against axial displacement;

wherein said transition duct favorably directs the output of the axial compressor into said inlet of the radial compressor and said exhaust cone section encloses sufficient volume to moderate the output of said radial compressor.

4. The supercharger as claimed in claim **3**, wherein said exhaust cone portion has a half-apex angle of approximately 35°.

5. The supercharger as claimed in claim **3**, wherein said transition duct has a half-apex angle of 35°.

6. The supercharger as claimed in claim **3**, wherein said transition duct is substantially coaxial with said inlet of the radial compressor.

7. The supercharger as claimed in claim **3**, wherein said axial compressor comprises a hub, a plurality of blades extending radially from said hub and a shroud connected to tips of said blades.

[57] ABSTRACT

The present invention relates to a method and apparatus for operating an engine having a cylinder and a piston reciprocable therein on compressed gas. The apparatus comprises a source of compressed gas connected to a distributor which distributes the compressed gas to the cylinder. A valve is provided to selectively admit compressed gas to the cylinder when the piston is in an approximately top dead center position. In one embodiment of the present invention the timing of the opening of the valve is advanced such that the compressed gas is admitted to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases. In a further embodiment of the present invention a valve actuator is provided which increases the length of time over which the valve remains open to admit compressed gas to the cylinder as the speed of the engine increases. A still further embodiment of the present invention relates to an apparatus for adapting a conventional internal combustion engine for operation on compressed gas.

METHOD AND APPARATUS FOR OPERATING AN ENGINE ON COMPRESSED GAS

BACKGROUND AND SUMMARY OF THE PRESENT INVENTION

The present invention relates to a method and apparatus for operating an engine using a compressed gas as the motive fluid. More particularly, the present invention relates to a apparatus for adapting a pre-existing internal combustion engine for operation on a compressed gas.

Air pollution is one of the most serious problems facing the world today. One of the major contributors to air pollution is ordinary internal combustion engine which are used in most motor vehicles today. Various devices, including many items mandated by legislation, have been proposed in an attempt to limit the pollutants which an internal combustion engine exhausts to the air. However, most of these devices have met with limited success and are often both prohibitively expensive and complex. A clean alternative to the internal combustion engine is needed to power vehicles and other machinery.

A compressed gas, preferably air, would provide an ideal motive fluid for a engine since it would eliminate the usual pollutants exhausted from an internal combustion engine. An apparatus for converting an internal combustion engine for operation on compressed air is disclosed in U.S. Pat. No. 3,885,387 issued May 27, 1975 to Simington. The Simington patent discloses an apparatus including a source of compressed air and a rotating valve actuator which opens and closes a plurality of mechanical poppet valves. The valves deliver compressed air in timed sequence to the cylinders of an engine through adapters located in the spark plug holes. However, the output speed of an engine of this type is limited by the speed of the mechanical valves and the fact that the length of time over which each of the valves remains open cannot be varied as the speed of the engine increases.

Another apparatus for converting an internal combustion engine for operation on steam or compressed air is disclosed in U.S. Pat. No. 4,102,130 issued July 25, 1978 to Stricklin. The Stricklin patent discloses a device which changes the valve timing of a conventional four stroke engine such that the intake and exhaust valves open once for every revolution of the engine instead of once every other revolution of the engine. A reversing valve is provided which delivers live steam or compressed air to the intake valves and is subsequently reversed to allow the exhaust valves to deliver the expanded steam or air to the atmosphere. A reversing valve of this type however does not provide a reliable apparatus for varying the amount of motive fluid injected into the cylinders when it is desired to increase the speed of the engine. Further, a device of the type disclosed in the Stricklin patent requires the use of multiple reversing valves if the cylinders in a multi-cylinder engine were to be fired sequentially.

Therefore, it is an object of the present invention to provide a reliable method and apparatus for operating an engine or converting an engine for operation with a compressed gas.

A further object of the present invention is to provide a method and apparatus which is effective to deliver a constantly increasing amount of compressed gas to an engine as the speed of the engine increases.

A still further object of the present invention is to provide a method and apparatus which will operate an engine using compressed gas at a speed sufficient to drive a conventional automobile at highway speeds.

It is still a further object of the present invention to provide a method and apparatus which is readily adaptable to a standard internal combustion engine to convert the internal combustion engine for operation with a compressed gas.

Another object of the invention is to provide a method and apparatus which utilizes cool expanded gas, exhausted from a compressed gas engine, to operate an air conditioning unit and/or an oil cooler.

These and other objects are realized by a method and apparatus according to the present invention for operating an engine having at least one cylinder and a reciprицating piston therein using compressed gas as a motive fluid. The apparatus includes a source of compressed gas and a distributor connected with the source of the compressed gas for distributing the compressed gas to the at least one cylinder. A valve is provided for admitting the compressed gas to the cylinder when the piston is in approximately a top dead center position within the cylinder. An exhaust is provided for exhausting the expanded gas from the cylinder as the piston returns to approximately the top dead center position.

In a preferred embodiment of the present invention a device is provided for varying the duration of each engine cycle over which the valve remains open to admit compressed gas to the cylinder dependent upon the speed of the engine. In a further preferred embodiment of the present invention, an apparatus for advancing the timing of the opening of the valve is arranged to admit the compressed gas to the cylinder progressively further before the top dead center position of the piston as the speed of the engine increases.

Further features of the present invention include a valve for controlling the amount of compressed gas admitted to the distributor. Also, a portion of the gas which has been expanded in the cylinder and exhausted through the exhaust valve is delivered to a compressor to be recompressed and returned to the source of compressed gas. A gear train is selectively engagable to drive the compressor at different operating speed depending upon the pressure maintained at the source of compressed air and/or the speed of the engine. Still further, a second portion of the exhaust gas is used to cool a lubricating fluid for the engine or to operate an air conditioning unit.

In a preferred embodiment of the present invention, the valve for admitting compressed gas to the cylinder is electrically actuated. The device for varying the duration of each engine cycle over which the intake valve remains open as the speed of the engine increase comprises a rotating element whose effective length increases as the speed of the engine increases such that a first contact on the rotating element is electrically connected to a second contact for a longer period of each engine cycle. The second contact actuates the valve whereby the valve remains in an open position for a longer period of each engine cycle as the speed of the engine increases.

Still further features of the present invention include an adaptor plate for supporting the distributor above an intake manifold of a conventional internal combustion engine after a carburetor has been removed to allow air

to enter the cylinders of the engine through the intake manifold and conventional intake valves. Another adaptor plate is arranged over an exhaust passageway of the internal combustion engine to reduce the cross-sectional area of the exhaust passageway.

BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of a method and apparatus for operating an engine according to the present invention will be described with reference to the accompanying drawings wherein like members bear like reference numerals and wherein:

FIG. 1 is a schematic representation of an apparatus according to the present invention arranged on an engine;

FIG. 2 is a side view of one embodiment of a valve actuator according to the present invention;

FIG. 3 is a cross-sectional view taken along the line 3—3 in FIG. 2;

FIG. 4 is a cross-sectional view of a second embodiment of a valve actuator according to the present invention;

FIG. 5 is a view taken along the line 5—5 in FIG. 4;

FIG. 6 is a cross-sectional view of a third embodiment of a valve actuator according to the present invention;

FIG. 7 is a view taken along the line 7—7 in FIG. 6;

FIG. 8 is a cross-sectional view of a gearing unit to drive a compressor according to the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to FIG. 1, an engine block **21** (shown in phantom) having two banks of cylinders with each bank including cylinders **20** having pistons **22** reciprocable therein (only one of which is shown in phantom) in a conventional manner. While the illustrated engine is a V-8 engine, it will be apparent that the present invention is applicable to an engine having any number of pistons and cylinders with the V-8 engine being utilized for illustration purposes only. A compressed gas tank **23** is provided to store a compressed gas at high pressure. It may also be desirable to include a small electric or gas compressor to provide compressed gas to supplement the compressed gas held in the tank **23**. In a preferred embodiment, the compressed gas is air which can be obtained from any suitable source.

A line **25** transports the gas withdrawn from the tank **23** when a conventional shut off valve **27** is open. In addition, a solenoid valve **29** preferably operated by a suitable key operated switch (not shown) for the engine is also arranged in the line **25**. In normal operation, the valve **27** is maintained open at all times with the solenoid valve **29** operating as a selective shut off valve to start and stop the engine **21** of the present invention.

A suitable regulating valve **31** is arranged downstream from the solenoid valve **29** and is connected by a linkage **33** to a throttle linkage **35** which is operator actuated by any suitable apparatus such as a foot pedal (not shown). The line **25** enters an end of a distributor **33** and is connected to an end of a pipe **35** which is closed at the other end. A plurality of holes, which are equal to the number of cylinders in the engine **21**, are provided on either side of the pipe **35** along the length of the pipe **35**.

When the present invention is used to adapt a conventional internal combustion engine for operation on compressed gas, an adaptor plate **36** is provided to support the distributor **33** in spaced relation from the usual intake opening in the intake manifold of the engine after a conventional carburetor has been removed. In this way, air is permitted to enter the internal combustion engine through the usual passageways and to be admitted to the cylinders through suitable intake valves (not shown). The adaptor plate **36** is secured to the engine block **21** and the distributor **33** by any suitable apparatus, e.g., bolts.

Each of the holes in the pipe **35** is connected in fluid-tight manner to a single line **37**. Each line **37** carries the compressed gas to a single cylinder **20**. In a preferred embodiment, each of the lines **37** is ½ inch high pressure plastic tubing attached through suitable connectors to the distributor **33** and the pipe **35**. Each of the lines **37** is connected to a valve **39** which is secured in an opening provided near the top of each of the cylinders **20**. In the case of a conversion of a standard internal combustion engine, the valves **39** can be conveniently screwed into a tapped hole in the cylinder **20** typically provided for a spark plug of the internal combustion engine. In a preferred embodiment, the valves **39** are solenoid actuated valves in order to provide a fast and reliable opening and closing of the valves **39**.

Each of the valves **39** is energized by a valve actuator **41** through one of a plurality of wires **43**. The valve actuator **41** is driven by a shaft of the engine similar to the drive for a conventional distributor of an internal combustion engine. That is, a shaft **55** of the valve actuator **41** is driven in synchronism with the engine **21** at one half the speed of the engine **21**.

A first embodiment of the valve actuator **41** (FIGS. 2 and 3) receives electrical power through a wire **45** which is energized in a suitable manner by a battery, and a coil if necessary (not shown) as is conventional in an internal combustion engine. The wire **45** is attached to a central post **47** by a nut **49**. The post **47** is connected to a conducting plate **51** arranged within a housing **53** for the valve actuator **41**. Within the housing **53**, the shaft **55** has an insulating element **57** secured to an end of the shaft **55** for co-rotation therewith when the shaft **55** is driven by the engine **21**. A first end of a flexible contact **59** is continuously biased against the conducting plate **51** to receive electricity from the battery or another suitable source. A second end of the contact **59** is connected to a conducting sleeve **60** which is in constant contact with a spring biased contact **61** which is arranged within the sleeve **60**. The contact **61** is biased by a spring **63** which urges the contact **61** towards a side wall of the housing **53**.

With reference to FIG. 3, a plurality of contacts **65** are spaced from one another and are arranged around the periphery of the housing **53** at the same level as the spring biased contact **61**. Each contact **65** is electrically connected to a post **67** which extends outside of the housing **53**. The number of contacts **65** is equal to the number of cylinders in the engine **21**. One of the wires **43**, which actuate the valves **39**, is secured to each of the posts **67**.

In operation, as the shaft **55** rotates in synchronism with the engine **21**, the insulating element **57** rotates and electricity is ultimately delivered to successive ones of the contacts **65** and wires **43** through the spring biased contact **61** and the flexible contact **59**. In this way, each of the electrical valves **39** is actuated and opened in the proper timed sequence to admit compressed gas to each of the cylinders **20** to drive the pistons **22** therein on a downward stroke.

The embodiment illustrated in FIGS. 2 and 3 is effective to actuate each of the valves 39 to remain open for a long enough period of time to admit sufficient compressed gas to each of the cylinders 20 of the engine 21 to drive the engine 21. The length of each of the contacts 65 around the periphery of the housing 53 is sufficient to permit the speed of the engine to be increased when desired by the operator by moving the throttle linkage 35 which actuates the linkage 33 to further open the regulating valve 31 to admit more compressed gas from the tank 23 to the distributor 33. However, it has been found that the amount of air admitted by the valves 39 when using the first embodiment of the valve actuator 41 (FIGS. 2 and 3) is substantially more than required to operate the engine 21 at an idling speed. Therefore, it may be desirable to provide a valve actuator 41 which is capable of varying the duration of each engine cycle over which the solenoid valves 39 are actuated, i.e., remain open to admit compressed gas, as the speed of the engine 21 is varied.

A second embodiment of a valve actuator 41 which is capable of varying the duration of each engine cycle over which each of the valves 39 remains open to admit compressed gas to the cylinders 20 dependent upon the speed of the engine 21 will be described with reference to FIGS. 4 and 5 wherein members corresponding to those of FIGS. 2 and 3 bear like reference numerals. The wire 45 from the electrical source is secured to the post 47 by the nut 49. The post 47 has a annular contact ring 69 electrically connected to an end of the post 47 and arranged within the housing 53. The shaft 55 rotates at one half the speed of the engine as in the embodiment of FIGS. 2 and 3.

At an upper end of the shaft 55, a splined section 71 slidably receives an insulating member 73. The splined section 71 of the shaft 55 positively holds the insulating member 73 for co-rotation therewith but permits the insulating member 73 to slide axially along the length of the splined section 71. Near the shaft 55, a conductive sleeve 72 is arranged in a bore 81 in an upper surface of the insulating element 73 generally parallel to the splined section 71. A contact 75, biased towards the annular contact ring 69 by a spring 77, is arranged within the conductive sleeve 72 in contact therewith. The conductive sleeve 72 also contacts a conductor 79 at a base of the bore 81.

The conductor 79 extends to the upper surface of the insulating element 73 near an outer periphery of the insulating element 73 where the conductor 79 is electrically connected to a flexible contact 83. The flexible contact 83 selectively engages a plurality of radial contacts 85 arranged on an upper inside surface of the housing 53. A weak spring 87 arranged around the splined section 71 engages a stop member 89 secured on the shaft 55 and the insulating element 73 to slightly bias the insulating element 73 towards the upper inside surface of the housing 53 to ensure contact between the flexible contact 83 and the upper inside surface of the housing 53. As best seen in FIG. 5, the radial contacts 85 on the upper inside surface of the housing 53 are arranged generally in the form of radial spokes extending from the center of the housing 53 with the number of contacts being equal to the number of cylinders 20 in the engine 21. The number of degrees covered by each of the radial contacts 85 gradually increases as the distance from the center of the upper inside surface of the housing 53 increases.

In operation of the device of FIGS. 4 and 5, as the shaft 55 rotates, electricity flows along a path through the wire 45 down through post 47 to the annular contact member 69 which is in constant contact with the spring biased contact 75. The electrical current passes through the conductive sleeve 72 to the conductor 79 and then to the flexible contact 83. As the flexible contact 83 rotates along with the insulating member 73 and the shaft 55, the tip of the flexible contact 83 successively engages each of the radial contacts 85 on the upper inside of the housing 53. As the speed of the shaft 55 increases, the insulating member 73 and the flexible contact 83 attached thereto move upwardly along the splined section 71 of the shaft 55 due to the radial component of the splines in the direction of rotation under the influence of centrifugal force. As the insulating member 73 moves upwardly, the flexible contact 83 is bent such that the tip of the contact 83 extends further radially outwardly from the center of the housing 53 (as seen in phantom lines in FIG. 4). In other words, the effective length of the flexible contact 83 increases as the speed of the engine 21 increases.

As the flexible contact 83 is bent and the tip of the contact 83 moves outwardly, the tip remains in contact with each of the radial contacts 85 for a longer period of each engine cycle due to the increased angular width of the radial contacts with increasing distance from the center of the housing 53. In this way, the length of time over which each of the valves 39 remains open is increased as the speed of the engine is increased. Thus, a larger quantity of compressed gas or air is injected into the cylinders as the speed increases. Conversely, as the speed decreases and the insulating member 73 moves downwardly along the splined section 71, a minimum quantity of air is injected into the cylinder due to the shorter length of the individual radial contact 85 which is in contact with the flexible contact 83. In this way, the amount of compressed gas that is used during idling of the engine 21 is at a minimum whereas the amount of compressed gas which is required to increase the speed of the engine 21 to a level suitable to drive a vehicle on a highway is readily available.

With reference to FIGS. 6 and 7, a third embodiment of a valve actuator 41 according to the present invention includes an arcuate insulating element 91 having a first end pivotally secured by any suitable device such as screw 92 to the shaft 55 for co-rotation with the shaft 55. The screw 92 is screwed into a tapped hole in the insulating element 91 such that a tab 94 at an end of the screw 92 engages a groove 96 provided in the shaft 55. In this way, the insulating element 91 positively rotates with the shaft 55. However, as the shaft 55 rotates faster, a second end 98 of the insulating element 91 is permitted to pivot outwardly under the influence of centrifugal force because of the groove 96 provided in the shaft 55. A spring 93 connected between the second end 98 of the element 91 and the shaft 55 urges the second end of the element 91 towards the center of the housing 53.

A contact 99 similar to the contact 59 (FIG. 2) is arranged such that one end of the contact 99 is in constant contact with the conducting plate 51 located centrally within the housing 53. The other end of the contact 99 engages a conductive sleeve 101 arranged in bore 102. A contact element 95 is arranged in the conductive sleeve 101 in constant contact with the sleeve 101. The bore 102 is arranged generally parallel to the shaft 55 near the second end of the arcuate insulating

element **91**. The contact **95** is biased by a spring **97** towards the upper inside surface of the housing **53** for selective contact with each of the plurality of radial contacts **85** which increase in arc length towards the outer peripheral surface of the housing **53** (FIG. **6**).

In operation of the device of FIGS. **6** and **7**, as the shaft **55** rotates the arcuate insulating element **91** rotates with the shaft **55** and the second end **98** of the insulating element **91** tends to pivot about the shaft **55** due to centrifugal force. Thus, as the effective length of the contact **95** increases, i.e., as the arcuate insulating element **91** pivots further outwardly, the number of degrees of rotation over which the contact **95** is in contact with each of the radial contacts **85** on the upper inside surface of the housing **53** increases thereby permitting each of the valves **39** to remain open for a longer period of each engine cycle to admit more compressed gas to the respective cylinder **20** to further increase the speed of the engine **21**.

With reference to FIG. **1**, a mechanical advance linkage **104** which is connected to the throttle linkage **35**, advances the initiation of the opening of each valve **39** such that compressed gas is injected into the respective cylinder further before the piston **22** in the respective cylinder **20** reaches a top dead center position as the speed of the engine is increased by moving the throttle linkage **35**. The advance linkage **104** is similar to a conventional standard mechanical advance employed on an internal combustion engine. In other words, the linkage **104** varies the relationship between the angular positions of a point on the shaft **55** and a point on the housing **53** containing the contacts. Alternatively, a conventional vacuum advance could also be employed. By advancing the timing of the opening of the valves **39**, the speed of the engine can more easily be increased.

The operation of the engine cycle according to the present invention will now be described. The compressed gas injected into each cylinder of the engine **21** drives the respective piston **22** downward to drive a conventional crankshaft (not shown). The movement of the piston downwardly causes the compressed gas to expand rapidly and cool. As the piston **22** begins to move upwardly in the cylinder **20** a suitable exhaust valve (not shown) arranged to close an exhaust passageway is opened by any suitable apparatus. The expanded gas is then expelled through the exhaust passageway. As the piston **22** again begins to move downwardly a suitable intake valve opens to admit ambient air to the cylinder. The intake valve closes and the ambient air is compressed on the subsequent upward movement of the piston until the piston reaches approximately the top dead center position at which time the compressed gas is again injected into the cylinder **20** to drive the piston **22** downward and the cycle begins anew.

In the case of adapting a conventional internal combustion engine for operation on compressed gas, a plurality of plates **103** are preferably arranged over an end of the exhaust passageways in order to reduce the outlet size of the exhaust passageways of the conventional internal combustion engine. In the illustrated embodiment, a single plate having an opening in the center is bolted to the outside exhaust passageway on each bank of the V-8 engine while another single plate having two openings therein is arranged with one opening over each of the interior exhaust passageways on each bank of the V-8 engine. A line **105** is suitably attached to each of the adaptor places to carry the exhaust to an appropriate location. In a preferred embodiment, the exhaust lines **105** are 1½" plastic tubing.

In a preferred embodiment, the exhaust lines **105** of one bank of the V-8 engine are collected in a line **107** and fed to an inlet of a compressor **109**. The pressure of the exhaust gas emmanating from the engine **21** according to the present invention is approximately 25 p.s.i. In this way, the compressor **109** does not have to pull the exhaust into the compressor since the gas exhausted from the engine **21** is at a positive pressure. The positive pressure of the incoming fluid increases the efficiency and reduces wear on the compressor **109**. The exhaust gas is compressed in the compressor **109** and returned through a line **111** and a check valve **113** to the compressed gas storage tank **23**. The check valve **113** prevents the flow of compressed gas stored in the tank **23** back towards the compressor **109**.

A suitable pressure sensor **115** is arranged at an upper end of the tank **23** and sends a signal along a line **117** when the pressure exceeds a predetermined level and when the pressure drops below a predetermined level. The line **117** controls an electrically actuated clutch **119** disposed at a front end of the compressor **109**. The clutch **119** is operative to engage and disengage the compressor **109** from a drive pulley **121**. Also, the signal carried by the line **117** actuates a suitable valve **123** arranged on a compressor housing **125** to exhaust the air entering the compressor housing **125** from the line **107** when the clutch **119** has disengaged the compressor **109** from the drive pully **121**.

In a preferred embodiment, when the pressure is the tank **23** reaches approximately 600 p.s.i., the clutch **119** is disengaged and the compressor **109** is deactivated and the valve **123** is opened to exhaust the expanded gas delivered to the compressor **109** from the line **107** to the atmosphere. When the pressure within the tank **23** drops below approximately 500 p.s.i., the sensor **115** sends a signal to engage the clutch **119** and close the valve **123**, thereby operating the compressor **109** for supplying the tank **23** with compressed gas.

The pulley **121** which drives the compressor **109** through the clutch **119** is driven by a belt **127** which is driven by a pulley **129** which operates through a gear box **131**. With reference to FIGS. **1** and **8**, a second pulley **133** on the gear box is driven by a belt **135** from a pulley **137** arranged on a drive shaft **139** of the engine **21**. The pulley **137** drives a splined shaft **140** which has a first gear **141** and a second larger gear **143** arranged thereon for rotation with the splined shaft **140**. The splined shaft **140** permits axial movement of the gears **141** and **143** along the shaft **140**.

In normal operation (as seen in FIG. **8**), the first gear **141** engages a third gear **145** arranged on a shaft **147** which drives the pulley **129**. The shafts **140** and **147** are arranged in suitable bearings **149** arranged at each end thereof. When the speed of the engine **21** drops below a predetermined level, a suitable sensor **151** responsive to the speed of the drive shaft **139** of the engine **21** generates a signal which is transmitted through a line **153** to a solenoid actuator **155** arranged within the gear box **131**. The solenoid actuator **155** moves the first and second gears **141**, **143** axially along the splined shaft **140** to the right as seen in FIG. **8** such that the second, larger gear **143** engages a fourth smaller gear **157** which is arranged on the shaft **147**. The ratio of the second gear **143** to the fourth gear **157** is preferably approximately 3 to 1.

In this way, when the speed of the engine **21** drops below the predetermined level as sensed by the sensor **151** (which predetermined level is insufficient to drive the compressor **109** at a speed sufficient to generate the 500-600 pounds of pressure which is preferably in the tank **23**), the solenoid actuator **155** is energized to slide the gears **143**, **141** axially along the splined shaft **140** so that the second, larger gear **143** engages the fourth, smaller gear **157** to drive the pulley **129** and hence the compressor **109** at a higher rate of speed to generate the desired pressure. When the speed of the engine increases above the predetermined level, in a preferred embodiment approximately 1500 rpm, the solenoid actuator **155** is deactivated by the sensor **151** thereby moving the gears **143** and **141** to the left as seen in FIG. **8** such that the first gear **141** re-engages with the third gear **145** to effectuate a 1 to 1 ratio between the output shaft **139** of the engine **21** and the pulley **129**.

The other bank of the V-8 engine has its exhaust ports arranged with adapter plates **103** similar to those on the first bank. However, the exhaust from this bank of the engine **21** is not collected and circulated through the compressor **109**. In a preferred embodiment, a portion of the exhaust is collected in a line **159** and fed to an enlarged chamber **161**. A second fluid is fed through a line **163** into the chamber **161** to be cooled by the cool exhaust emmanating from the engine **21** in the line **159**. The second fluid in the line **163** may be either transmission fluid contained in a transmission associated with the engine **21** or a portion of the oil used to lubricate the engine **21**. A second portion of the exhaust from the second bank of the V-8 engine is removed from the line **159** in a line **165** and used as a working fluid in an air conditioning system or for any other suitable use.

It should be noted that the particular arrangement utilized for collecting and distributing the gas exhausted from the engine **21** would be determined by the use for which the engine is employed. In other words, it may be advantageous to rearrange the exhaust tubing such that a larger or smaller percentage of the exhaust is routed through the compressor **109**. It should also be noted that since the exhaust lines **105** are plastic tubing, a rearrangement of the lines for a different purpose is both simple and inexpensive.

In operation of the engine of the present invention, the engine **21** is started by energizing the solenoid valve **29** and any suitable starting device (not shown), e.g., a conventional electric starter as used on an internal combustion engine. Compressed gas from the full tank **23** flows through the line **25** and a variable amount of the compressed gas is admitted to the distributor **33** by controlling the regulator valve **31** through the linkage **33** and the operator actuated throttle linkage **35**. The compressed gas is distributed to each of the lines **37** which lead to the individual cylinders **20**. The compressed gas is admitted to each of the cylinders **20** in timed relationship to the position of the pistons within the cylinders by opening the valves **39** with the valve actuator **41**.

When it is desired to increase the speed of the engine, the operator moves the throttle linkage **35** which simultaneously admits a larger quantity of compressed gas to the distributor **33** from the tank **23** by further opening the regulator valve **31**. The timing of the valve actuator **41** is also advanced through the linkage **104**. Still further, as the speed of the engine **21** increases, the effective length of the rotating contact **83** (FIG. 4) or **95** (FIG. 6) increases thereby electrically contacting a wider portion of one of the stationary radial contacts **85** to cause each of the valves **39** to remain open for a longer period of each engine cycle to admit a larger quantity of compressed gas to each of the cylinders **20**.

As can be seen, the combination of the regulating valve **31**, the mechanical advance **104**, and the valve actuator **41**, combine to produce a compressed gas engine which is quickly and efficiently adaptable to various operating speeds. However, all three of the controls need not be employed simultaneously. For example, the mechanical advance **104** could be utilized without the benefit of one of the varying valve actuators **41** but the high speed operation of the engine may not be as efficient. By increasing the duration of each engine cycle over which each of the valves **39** remains open to admit compressed gas to each of the cylinders **20** as the speed increases, conservation of compressed gas during low speed operation and efficient high speed operation are both possible.

After the compressed gas admitted to the cylinder **20** has forced the piston **22** downwardly within the cylinder to drive the shaft **139** of the engine, the piston **22** moves upwardly within the cylinder **20** and forces the expanded gas out through a suitable exhaust valve (not shown) through the adapter plate **103** (if employed) and into the exhaust line **105**. The cool exhaust can then be collected in any suitable arrangement to be compressed and returned to the tank **23** or used for any desired purpose including use as a working fluid in an air conditioning system or as a coolant for oil.

When using the apparatus and method of the present invention to adapt a ordinary internal combustion engine for operation with compressed gas it can be seen that considerable savings in weight are achieved. For example, the ordinary cooling system including a radiator, fan, hoses, etc. can be eliminated since the compressed gas is cooled as it expands in the cylinder. In addition, there are no explosions within the cylinder to generate heat. Further reductions in weight are obtained by employing plastic tubing for the lines which carry the compressed gas between the distributor and the cylinders and for the exhaust lines. Once again, heavy tubing is not required since there is little or no heat generated by the engine of the present invention. In addition, the noise generated by an engine according to the present invention is considerably less than that generated by an ordinary internal combustion engine since there are no explosions taking place within the cylinders.

The principles of preferred embodiments of the present invention have been described in the foregoing specification. However, the invention which is intended to be protected is not to be construed as limited to the particular embodiments disclosed. The embodiments are to be regarded as illustrative rather than restrictive. Variations and changes may be made by others without departing from the spirit of the invention. Accordingly, it is expressly intended that all such variations and changes which fall within the spirit and the scope of the present invention as defined in the appended claims be embraced thereby.

What is claimed is:

1. An apparatus for operating an engine having at least one cylinder and a reciprocating piston therein comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder;

altering means for increasing the duration of each engine cycle over which the valve means admits compressed gas to the at least one cylinder as the speed of the engine increases; and

exhaust means for exhausting gas as the piston subsequently approaches approximately the top dead center position.

2. The apparatus of claim 1 further comprising control means for controlling the amount of compressed gas admitted to the distributor means.

3. The apparatus of claim 1 wherein the valve means is a solenoid valve secured in an opening in the cylinder above the level of the piston at the top dead center position.

4. The apparatus of claims 1 or 2 further comprising means for advancing the timing of the valve means as the speed of the engine increases such that compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

5. The apparatus of claim 4 wherein the means for advancing the timing comprises a mechanical linkage connected to an operator actuated accelerator linkage.

6. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is compressed in a compressor driven by an output shaft of the engine and is returned to the source of compressed gas.

7. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is used to cool transmission fluid for a transmission associated with the engine.

8. The apparatus of claim 1 wherein a portion of the gas exhausted through the exhaust means is used as a working fluid in an air conditioning system.

9. The apparatus of claim 6 further comprising first gearing means interposed between the output shaft of the engine and the compressor for increasing the speed at which the compressor is driven.

10. The apparatus of claim 6 further comprising clutch means attached to the compressor both for disengaging the compressor from the output shaft of the engine when a first predetermined pressure at the source of compressed gas is exceeded and for engaging the compressor with the output shaft of the engine when the pressure at the source of compressed gas drops below a second predetermined pressure.

11. The apparatus of claim 9 further comprising means for both disengaging the first gearing means when a predetermined speed of the engine is exceeded and engaging a second gearing means for driving the compressor at a speed slower than the first gearing means when the predetermined speed of the engine is exceeded.

12. The apparatus of claim 1 wherein the valve means is electrically actuated and wherein the altering means comprises:

a rotating member timed with the at least one cylinder and arranged within a housing;

first and second contacts arranged on a first end of the rotating member and on an inside surface of the housing, respectively;

means for increasing the distance of the first contact from the rotational axis of the rotating member as the speed of the engine increases such that the first contact moves radially outwardly within the housing; and

said second contact presenting a longer arc length to the first contact as the distance of the first contact from the rotational axis of the rotating member increases.

13. The apparatus of claim 12 wherein the rotating member comprises an arcuate arm and wherein the means for increasing the distance of the first contact comprises pivotally mounting a second end of the arcuate arm about the axis of rotation of the rotating member and spring means for biasing the first end of the arcuate arm towards a radially inward position whereby the first end of the arcuate arm pivots radially outwardly as the speed of the engine increases.

14. The apparatus of claim 12 wherein the rotating member is axially slidably received on a rotating shaft for co-rotation therewith, said shaft having splines with a radial component in the direction of rotation, and wherein the first contact comprises a flexible contact located on an upper surface of the rotating member, said flexible contact being biased against the inside surface of the housing which carries the second contacts whereby as the speed of the engine increases the rotating member is urged axially along the splined shaft towards the inside surface of the housing such that the flexible contact is forced radially outwardly along the inside surface.

15. The apparatus of claim 12 wherein the second contact comprises of radially extending conductor arranged on an upper inside surface of the housing, said conductor increasing in arc length as the conductor extends radially outwardly from a central portion of the housing.

16. An apparatus for adapting an internal combustion engine for operation with compressed gas, the internal combustion engine having at least one cylinder, a piston reciprocable within the at least one cylinder, intake and exhaust means disposed in the at least one cylinder, and a tapped hole in the at least one cylinder adapted to receive a spark plug, the apparatus comprising:

a source of compressed gas;

distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;

valve means arranged in the tapped hole for admitting the compressed gas to the at least one cylinder when the piston is in approximately a top dead center position within the cylinder; and

altering means for increasing the duration of each engine cycle over which the valve means remains open to admit the compressed gas as the speed of the engine increases.

17. An apparatus as in claim 16 further comprising first adapter plate means for supporting the distributor means above an intake manifold of the engine, which adaptor plate means allows ambient air to enter through the intake manifold.

18. The apparatus of claim 16 further comprising second adapter plate means for reducing the exit area of the exhaust means.

19. A method of operating an engine on compressed gas, said engine having at least one cylinder and a piston reciprocable therein comprising the steps of:

- delivering compressed gas from a source to a distributor;
- distributing the compressed gas to the at least one cylinder;
- admitting compressed gas to the at least one cylinder through an intake valve when the piston is at approximately a top dad center position;
- increasing the duration of each engine cycle over which compressed gas is admitted to the at least one cylinder as the engine speed increases; and
- exhausting the remaining gas when the piston subsequently reaches approximately the top dead center position.

20. The method of claim **19** further comprising the step of controlling the amount of compressed gas which is delivered to the distributor.

21. The method of claim **19** further comprising the step of advancing the timing of the opening of the intake valve as the speed of the engine increases.

22. An apparatus for operating an engine having at least one cylinder and a piston reciprocable therein on compressed gas comprising:

- a source of compressed gas;
- distributor means connected with the source of compressed gas for distributing the compressed gas to the at least one cylinder;
- electrically actuated valve means secured in an opening in the at least one cylinder for selectively admitting compressed gas to the at least one cylinder when the piston is in approximately a top dead center position; and
- means for advancing the timing of the valve means as the speed of the engine increases whereby compressed gas is admitted progressively further before the top dead center position as the speed of the engine increases.

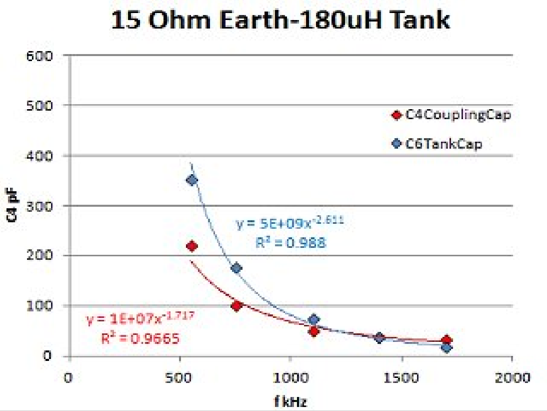
Antenna Tuning Unit Notes:

Back to Lab..



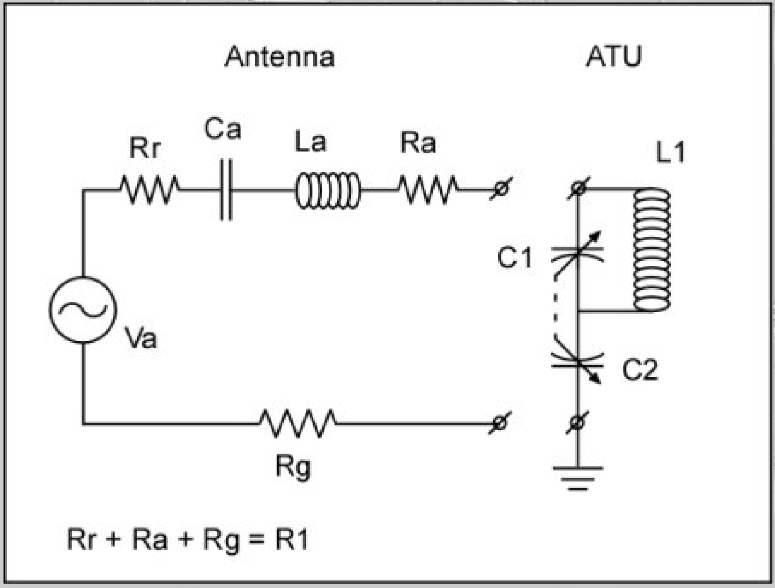
Introduction:

When designing my radios I always make extensive use of Mike Peebles and Dan Petersen's "Professor Coil" spreadsheet. This tool along with the many tutorials and explanations online have vastly eased the design work around homebrew coil winding. We can now model a coil with good accuracy prior to the actual job and thus better match the coil to the other components we plan to include. One quickly becomes aware that most coils for the broadcast band vary around a nominal 220 or so uH. More than this and most variable capacitors will have too much bottom-end capacitance to tune the top of the band. Less than this and you need caps with fairly high values when fully meshed, 500+pF or more.

All the above is pretty straight forward. On the other hand, when I have been reviewing double-tuned set designs, I often note that the coil used for the ATU (antenna tuning unit) will have an inductance quite a bit lower than the main tank coil. Professor Coil doesn't address this aspect of coil design and I have found little discussion online concerning ATU design. Mostly this seems to be dealt with in passing or as a digression when dealing with other subjects. The most useful web sites for addressing this aspect of crystal set design include Dick Kleijer's excellent work and Ramon Vargas's detailed analysis of the "Tuggle Front End", that's about it. Neither site discusses the ramifications of varying different parameters such as the Earth Resistance, Coil Inductance, etc although Kleijier's site includes a great calculator page to allow one to ask these questions. In my explorations of ATU design (primarily Tuggle) I have made extensive use of Kleijier'e page and for this I am deeply in his debt. My hat's off to Dick, thanks so much.

The following discussion presents the results of many models cranked through the design calculator. I wished to understand what factors play main roles and which have minor parts.

For a conventional detector-circuit coil one can pretty much control all the main factors, really only the inductance and capacitance of the circuit. The main and only surprise comes in the form of "stray capacitance" resulting from the spacing of the coil wires. This can readily be 1) guessed at and 2) minimized by good coil winding technique. For the antenna circuit by contrast many of the needed parameters, earth resistance, antenna capacitance and inductance, and antenna resistance in the forms of actual wire resistance and radiation resistance are, for most of us, unknown and only guessed at. The following figure illustrates the antenna and ATU with a list of the main "components" that need to be understood and/or modeled.



The Antenna consists of an AC voltage source (the signal of interest) Va, in series with some radiation resistance Rr, antenna capacitance Ca, antenna inductance La, antenna resistance Rr, and finally a ground resistance for the return path to complete the circuit. In addition the ATU consists of a coupling capacitance C2, and a tank with inductance L1 and capacitance C1. The capacitance and inductance of the ATU is needed to tune out the reactance of the various components of the antenna for which we do not have data. What to do?

Without an antenna analyzer (expensive) one can only estimate the many component values based on published antenna models. Ken Kuhn's engineering page has a number of nice models and a good discussion of the antenna parameters we will be trying to understand and use. For my personal setup my antenna consists of about 75' of 14awg wire averaging about 10-12' high and with another 25' of lead-in. For such an antenna Kuhn models a 30m antenna 3m high which approximates my situation closely enough. Wire resistance is negligible as is the radiation resistance which he shows to vary between some 0.1 to 1.5 ohms. Such an antenna is capacitive by nature and will have

about 220 - 375pF along with some small 20uH inductance, not too far off a standard "dummy" antenna. This pretty much leaves earth resistance Rg and the main unknown parameter.

For Rg one has the option of punting and taking the "Standard" value of 25 ohms. In my modeling I have found this parameter to be critical and highly sensitive. I do not recommend guessing here, it is recommended one go to the internet page of their state, county, or local government and search for reports on ground or soil resistivity (or conductivity). As this is an important agricultural and engineering parameter, it has been surveyed for most places and should be available with some effort. Effort well rewarded. Earth resistivity for the Texas Gulf Coast is a mercifully low 10 - 15 ohm meters, but for many regions this will not be the case.

Earth resistivity depends on a number of variables including the material, moisture, mineral salt, and temperature. A table of typical ranges in ohm meters for some different soils follows:

Loam	5 - 50 ohm meter
Clay	4 - 100
Sand/Gravel	50 - 1,000
Limestone	5 - 10,000
Sandstone	20 - 2,000
Granite	1,000 - 2,000
Slates	600 - 5,000

Moisture up to about 17% dramatically lowers resistivity, mineral salts are needed as pure water is an insulator, and as the temperature approaches freezing the resistivity also rises dramatically. All these factor into your estimation of Rg. The actual resistivity seen by the circuit depends on the earth resistivity and the type of grounding system you have installed. The more metal in the ground and deeper, the lower the resistance. Know thy earth! A map of USA soil resistivity follows:

FIGURE 2

Estimated Average Earth Resistivity in U.S. (ohm·meters)

Modeling:

All the above discussion is great but... What is important really? The following section presents the results of applying different parameters to get a feel for the sensitivity of it all. To begin with I need explain my base assumptions. All the models are based on Kleijer's calculation spreadsheet which requires inputs for the following parameters:

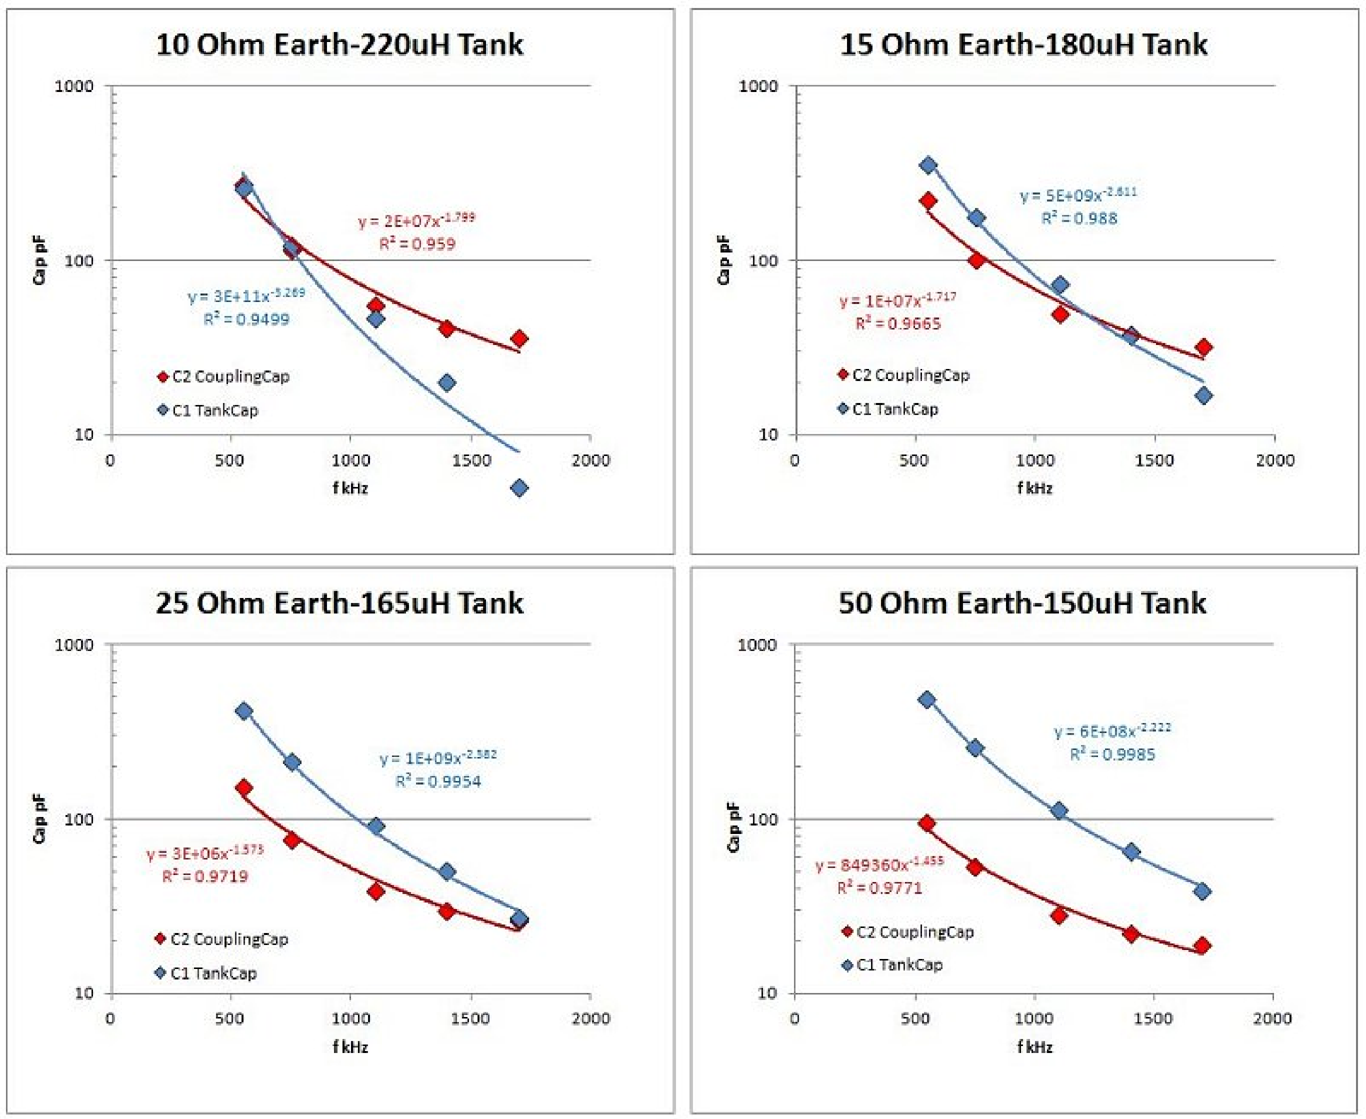
Frequency
Coil inductance
LC circuit Q unloaded
*** Complex impedance of antenna or**

Series Resistance (Rg+Ra+Rr)
Series Capacitance Ca
Series Inductance La

*** If the series values are given, the complex impedance is calculated.**

1) Frequency is chosen per your model, I have taken models at F = 550-1100-1700 kHz.
2) Coil inductance one has control over when winding. I have chosen base values that resonate with about 400pF tank capacitance, with some sensitivities.
3) Unloaded Q I do not have. For modeling I have taken Vargas's measures for a 4.5" coil wound with 660/46 Litz wire. I assume this will be about as good a coil as one can wind. I also made a sensitivity for lower Q. Q is a function of frequency and I have used the appropriate value of Q to match the modeled frequency.
4) Series Resistance is basically what the earth and ground system will deliver plus a small 1-2 ohm contribution from Ra and Rr. I have modeled four cases 10, 15, 25 and 50 ohms. The first two cases reflect my needs on the Gulf Coast with low resistivity soil. The 25 ohm case is a "typical" or "standard" ground. Finally, many will have much higher resistivity soils and you need to know just how difficult things can get!
5) Series capacitance I based for my specific antenna on the model of Ken Kuhn (Mathematical Model of Wire Antenna). The capacitance of a 30m antenna 3m high he calculated to range from 220pF and low frequencies to 375pF and high frequencies. I input the correct capacitance to match the frequency modeled.
6) Series inductance I just input 20 uH every time.

The data and plots for four different scenarios follow:



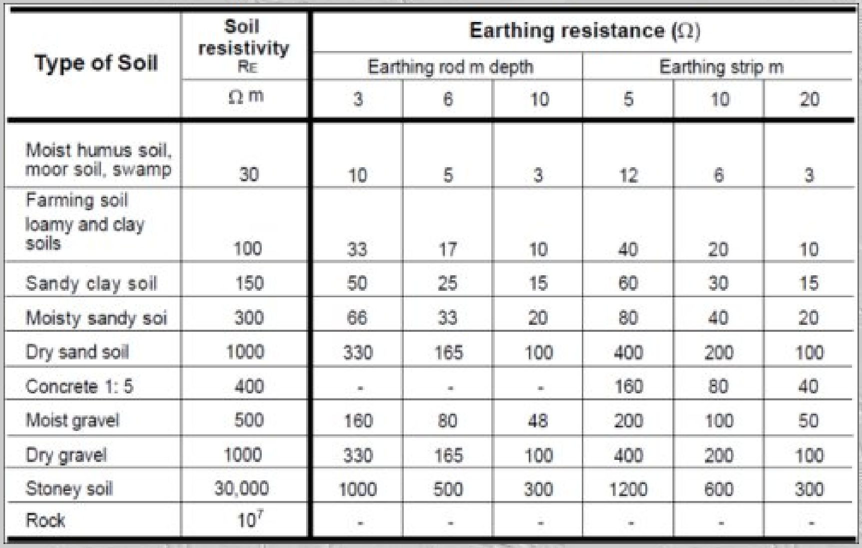
The above plots show the calculated capacitance versus frequency for four different models of Earth Resistivity / Tank Inductance. In each case I maintain the same log capacitance vs frequency scale for easy comparison. The cases modeled represent increasing earth resistance presented to the ATU from a very low 10 ohms to a fairly high 50 ohms. Actual earths

can go up to two orders of magnitude higher. I chose L1 inductances such that the maximum needed capacitance would approach 500pFs, easily found on many variable caps. With respect to the coupling cap (C2, red curve), as the earth resistivity increases, the needed capacitance declines. The tank cap value needs to resonate with the inductor and increases with smaller-value inductance. In searching for a 500pF cap max value, the choice of inductance needs to decrease with increasing earth resistance. Parameters other than Rg, L1 and C1-C2 have minor impact on the models.

Conclusions:

From the plots one can readily see that above 15 ohm earth the two variable capacitors on the ATU do not track well. As the earth resistivity increases, the worse the tracking. Most locations are not blessed with a low resistivity earth and this needs to be factored into the ATU design. There is little to be done, changing the design coil inductance will change the needed capacitance on BOTH C1 and C2, (larger L1 leads to smaller C1 and C2 for resonance and vice versa). A possible solution well worth trying is to use a dual-gang capacitor where one section has a different value than the other, the above plots give an easy way to decide the max values needed. Use the smaller gang on the coupling circuit and the larger on the tank. Experience tells us that ganging the capacitors on a "Tuggle" front end works well, but from the models I have to imagine one might squeeze a bit more performance by giving up the convenience of one-dial tuning on the ATU, especially where your earth has a fairly high resistance.

The best design methodology requires that you know first and critically your earth resistance. If this is just a guessed-at parameter then I strongly urge you to put down the Litz, set aside the silver-plated-ceramic-insulated caps, box the holy-grail diodes and go do some research on your local ground. All the time, expense, and effort on the greatest "state-of-the-art" crystal receiver will be wasted if the ground is not attended to. If the resistivity of your earth is high in ohm-meters, get more metal in the ground or consider a counter-poise. The following table from LEM Instruments shows the relation between earth resistivity in ohm meters and actual earth resistance in ohms as a function of the earthing method used.



Type of Soil	Soil resistivity R_E	Earthing resistance (Ω)					
		Earthing rod m depth			Earthing strip m		
	Ω m	3	6	10	5	10	20
Moist humus soil, moor soil, swamp	30	10	5	3	12	6	3
Farming soil loamy and clay soils	100	33	17	10	40	20	10
Sandy clay soil	150	50	25	15	60	30	15
Moisty sandy soi	300	66	33	20	80	40	20
Dry sand soil	1000	330	165	100	400	200	100
Concrete 1: 5	400	-	-	-	160	80	40
Moist gravel	500	160	80	48	200	100	50
Dry gravel	1000	330	165	100	400	200	100
Stoney soil	30,000	1000	500	300	1200	600	300
Rock	10^7	-	-	-	-	-	-

Given just how little discussion there is on the web concerning antenna tuning and the impact of ground resistivity I hope this page can serve as a starting point for further research. Certainly there is more to be said, Crystal Radio, its a bottomless pit!

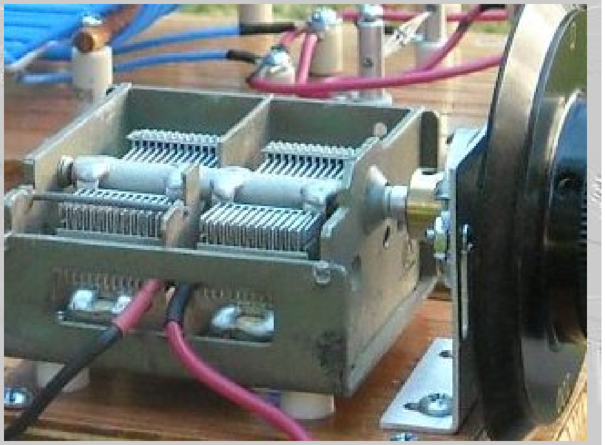
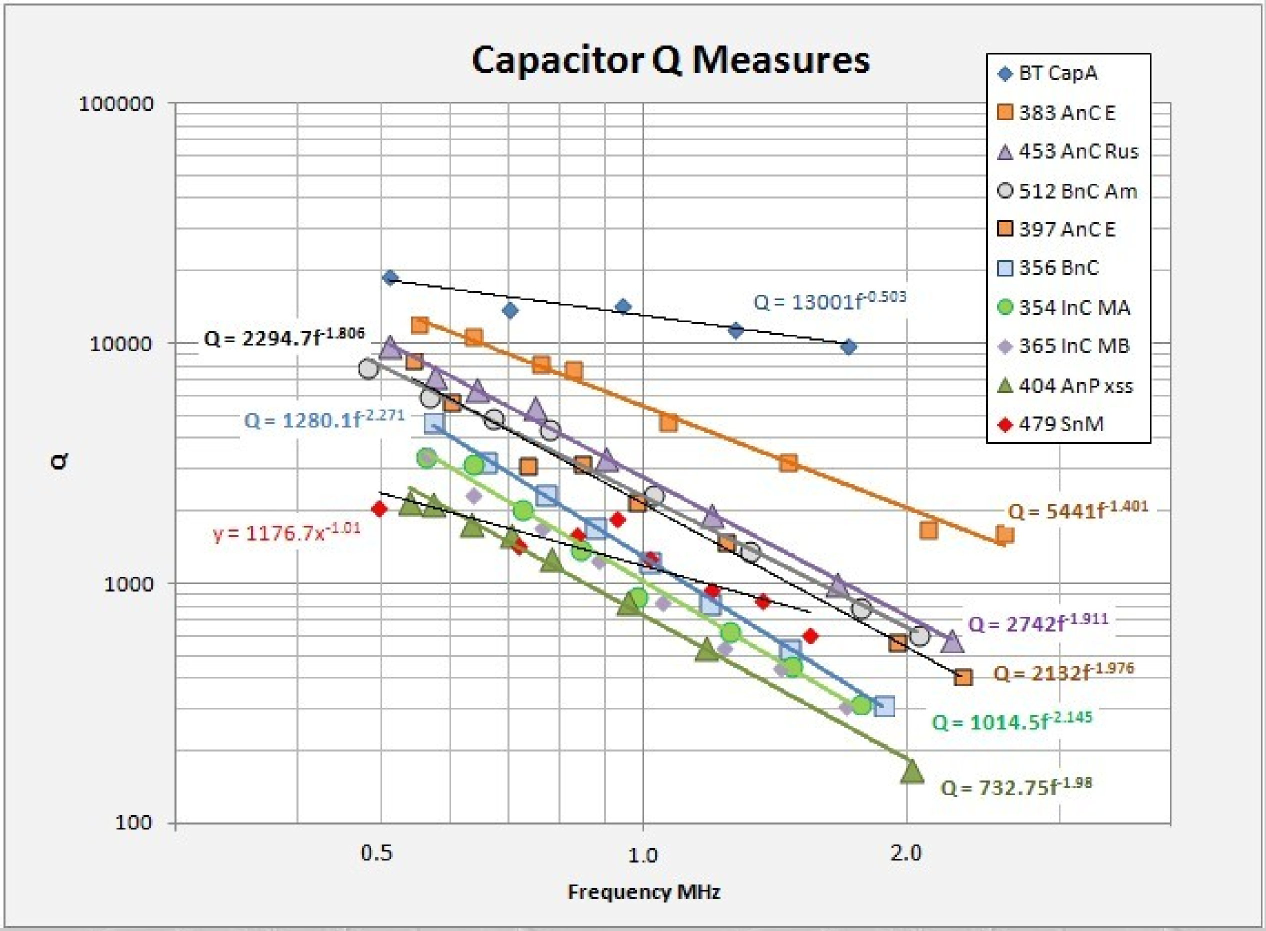
Crystal Radio Capacitors and ESR



Back to Lab..

In my ongoing effort to understand crystal radios and the theory that makes them work I have recently began looking into all things capacitance. The tuning capacitor is, next the coil itself, the principal component of the set. Since few builders fabricate their own tuning caps I suppose one takes them a bit for granted. I have been reading on the radio forums some threads concerning radio Q and the subject of the variable cap Q seems to be getting more attention. So, what is the deal?

I set about my study by gathering what I could find on the web and at the close of this note I include a short reference list of useful pages from which I extracted data the ideas. I wish to extend special thanks to Ben Tongue who, as usual, has provided essential measurements and background in his Article 24. The plot below shows capacitor Q versus frequency for a small number of air-variable capacitors that I have in the box. It is a standard plot with log Q versus log frequency in MHz. On the plot, a bit messy I admit, I show data for six capacitors along with the Q versus f equation. You immediately see that for each capacitor the relation follows a power function and in all cases the function is good to R-squared at or above 99%. Additionally, I include the same data for two capacitors presented in Ben Tongue's excellent summary. It is also immediately obvious that not all caps are created equal!



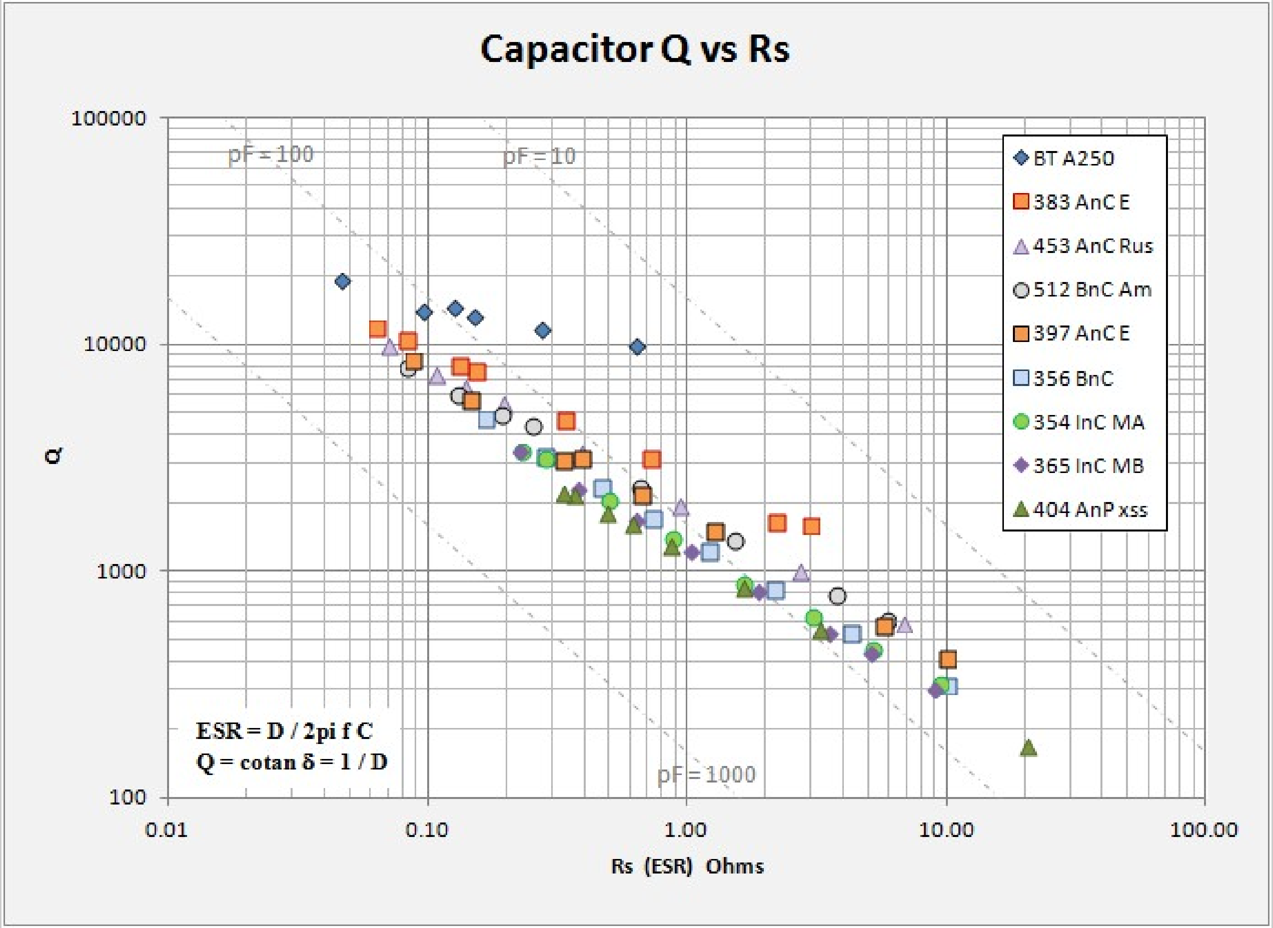
I have named the caps in the following manner, the highest tested RF capacitance, materials of interest (A = aluminum plates, B = brass plates; C = ceramic insulators, P = phenolic insulators); finally something to do with the origin. Photos of the caps at the bottom of this page.

Identification of the caps as follows (from highest to lowest Q):

BT CapA	Ben Tongue's CapA is the best "Holy Grail" of the lot
383 AnC E	A Russian (I presume) eBay cap from Estonia
453 AnC Rus	A Russian cap frequently offered on eBay
512 BnC Am	A brass straignt-line frequency cap AMSOO
397 AnC E	Another Russian (I presume) eBay cap from Estonia, larger capacitance
356 BnC	Another Lovely straight-line frequency brass cap
354 InC M	Chinese caps (A and B) offered from Ming on eBay
404 AnC xss	A typical Crystal Set Society cap
479 SnM	Switched set of individual Silver Mica caps, not an air-variable

Any discussion of component quality needs first to acknowledge that the fight to increase the component Q is in reality a fight to eliminate (not possible) or reduce as much as feasible the resistive losses associated with that component. It helps then to look not just at Q, but at how Q relates to the component series resistance Rs or ESR. There are two fundamental equations that describe this relation: 1) Q = cotan theta = 1/D. D is the dissipation factor and is an attribute of the dielectric material used in the construction of the capacitor. D = tan theta = ESR / Xc = 2pi f C * ESR. Solving for ESR we get: 2) ESR = D / 2pi f C. This equation tells us that capacitor losses expected due to resistance are dependant on both angular frequency and capacitance. It is important to remember that not all Q's are created equal. What we want is to keep the ESR to a minimum.

The plot below summarizes the same data only this time plotting log Q versus log Rs (ESR). Here most of the data sets fall into a narrow zone running from High-Q / low ESR in the upper left to Low-Q / high ESR in the lower right. Ben Tongue's Holy Grail cap sits above the pack with an overall narrower range of ESR from max to min capacitance. No surprises, good caps are low-loss. I have also plotted lines of Q versus ESR at 1MHz for threee capacitance values, 10, 100, and 1000 pF. These lines indicate that Q is highest at high values of capacitance independant of individual capacitor loss. Note that all the caps measured straddle the 100 pF line. For typical MW coils with about 230 uH or so, 100 pF resonates around 1MHz.



From the datasets above it can be seen that high-Q caps are high-Q across the band, but Q varies and is highest at high capacitance, (lower frequency) and vice versa. All sets show a direct power-law relation between Q and f or ESR

regardless of overall quality or type of capacitor. The data table from Ben Tongue (below) was found in his Article 24 and represent precision measuremnts by Bill Hebbert.

pF		f	Q		
cap	tank	MHz	Cap A	Cap B	
355	375	520	19000	4750	
170	190	730	14000	3230	
94	114	943	14400	1610	
81	101	1000	13148	1828	(my estimate)
40	60	1300	11600	870	
15	35	1710	9800	460	

for I = 250 uH and 20pF stray in tank

Some notes on my results. It should be immediately clear that I have yet to snag an actual "holy grail" cap such as the one evaluated by Ben Tongue. Ben's good CapA has ceramic insulated stators and silver-plated brass plates with silver-plated wiper contacts. Essential features of a good cap. Inexpensive caps often have lossy phenolic insulators, something easily noticeable before you buy, look for this. I have noticed that on some caps the stator is held by ceramic "buttons" rather than a large ceramic plate and I have to wonder how effective this is. I would say that ceramic insulation is far more available that silver plating on the plates and wipers.

At the bottom end of the quality profile is the poor but readily available XSS variable cap (404 AnP). This has aluminum plates, phenolic insulation and a single aluminum wiper. An OK basic cap, but one easily beat if you are willing to make an effort. Next up in terms of quality was a big disappointment for me. These are two Chinese caps I recently purchased on eBay (354 and 365 InC). They are large and heavy units with big ceramic insulators and I figured this ought to be good. Both caps have decidedly lower Q that my vintage brass straight-line frequency caps. I do not think these will find their way into any radios here.

In the mid-Q range I find one brass cap (512 BnC) and two Russian caps (453 AnC, and 397 AnC). These all have ceramic insulation but no silver plating. The brass cap insulators are a black material that I call ceramic as it does not appear phenolic, but frankly I am unsure what it is. The cap is pretty good though. The two Russian caps are commonly available on eBay and are of two different styles. One somewhat large with thick "gun metal" type casing and the other a small delicate unit with a plastic dust-cover. Both are pretty good caps.

Finally and best cap that I have in my box is another Russian cap (383 AnC). This cap is clearly an unused NOS unit with clean shiny parts and button ceramic insulators. This is a slightly smaller version of one of the previous caps (397 AnC). The moderate Q version was also clean and NOS, so I do not expect all such caps to be automatically good Q. It is a pity as I have seen additional of these small caps on eBay, though clearly in used condition so I suspect they will have lower Q.

From all the above I would conclude that caps having ceramic insulation alone is not nirvana. Caps need also to be clean and ultimately need silver plating to truly aspire to "holy grail" status. A good reference worth looking at is a thread on The Radio Board: Improving 'Q' of capacitors.
The post shows how merely taking an older cap and cleaning it up (no small task) and replacing the insulators with HDPE sheet (high-density polyethylene) can take an original Q = 664 (1MHz) and raise it to Q = 12248 (1MHz). This value is on par with Ben Tongue's "holy grail" cap (Q = 13148 @ 1MHz) and either it was a dim fine cap to start with or something not fully kosher with the measurements. Still, the point is that improvements can be significant.

Images of the tested caps, same scale.

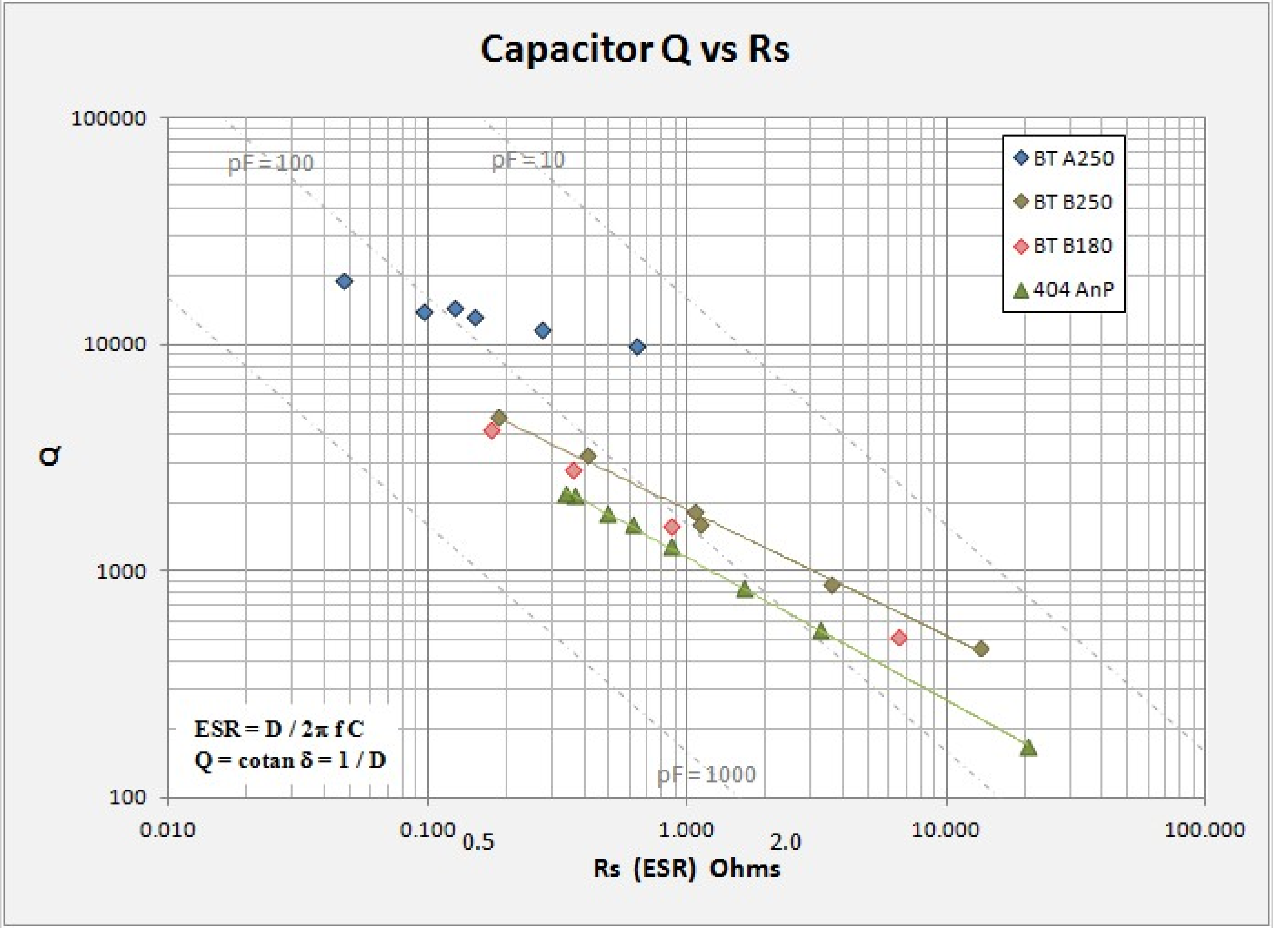
A short note concerning my Q measurements as compared to those of Bill Hebbert and presented by Ben Tongue in his Article 24. By some chance, both Ben's work as well as my own include a commonly available 365 pF capacitor from the XSS and elsewhere. While his cap and my own are not the same cap, they ought to be similar enough. Therefore it is worth to take a look ar the two datasets together.

In the plot below of Q vs ESR I show Ben's three measurement sets as well as my own measuremnts on the same type cap. Ben's A250 (holy grail) is included just for show. His measurements on CapB were made with two separate inductors, one with 250 uH and one with 180 uH. My standard inductor has 225 uH. On the plot I include a trend for Ben's 250 uH and my 225 uH data. It is clear that my measurements are systematically lower than his.

At this time I am uncertain as to whether my setup delivers lower Q measurements or if the partictular cap I measured was a bit more lossy than Ben's. This is a bit of ambiguity in my presentation that the reader ought to be aware of. Maybe my caps are better than presented? I do not know the answer but I include this plot just so you know.



A note concerning Loss Tangent

When looking into capacitor losses one often runs into the term "loss tangent". For many our eyes just glaze over and we read on understanding only that it has something interesting to do with theory. In the interest of knowing the code I give a brief explanation.

With a perfect lossless capacitor in AC operation (sine wave) current leads the voltage by 90 degrees. Where losses occur the current will lead by slightly less than this. If you imagine these losses as a resistance in series with a perfect

capacitor, then this is called Effective Series Resistance, ESR and is valid in reference to a specific frequency: ESR = D / 2pi * f * C.

The lag angle between current and voltage is generally a fraction of a degree and is expressed as a positive value. The tangent of this lag angle is the "loss tangent" and is referred to more commonly as the Dissipation factor D. For example, polystyrene has a D of about 0.0001 for a lag angle of 0.006 degrees. Good dielectrics have very small loss tangents. Why do we express loss as D or loss tangent? Well, it related to the quality factor Q such that Q = 1/D.

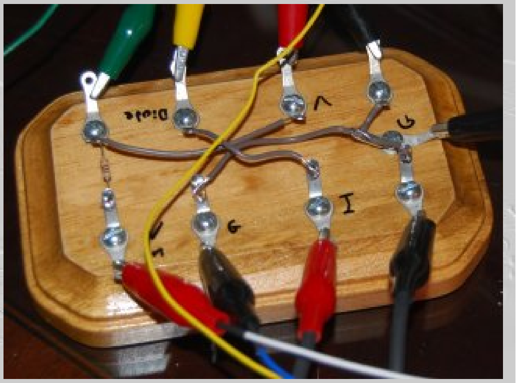
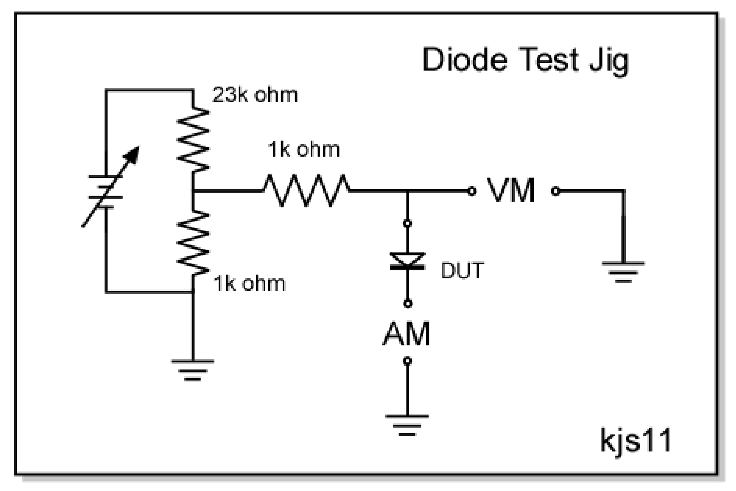
Part I: Diode Test and Protocol



Back to Lab..

The following explains my first attempt to compare a measured diode characteristics with calculated plots based on the Shockley Equation.

I have been taking a serious look into diode modeling and measurement recently in an attempt to better understand these solid-state successors to the humble crystal and cat's whisker detector. There is much good information on diodes to be found in many excellent web sites of course, but there is nothing quite like actually making the measurements and working with them to get a good feel. This page reports some of my protocols and test setups which I have found to be useful.



This is a very simple circuit allowing power input, attaching a diode for testing, and sampling both the curent and voltage across the diode under test, (DUT). I made a simple modification by adding a voltage divider, about 20:1 at the power input. The power supply can be connected either at the front across the divider, or after the divider in front of the 100k current limiting resistor for higher voltage readings. I get the input voltage from a modest 18V, 2A regulated DC power supply. This unit has both volt and amp controls with digital readouts, nice to use and doesn't take up much room on my desk. Here is a case where I recommend you look at getting a new unit. I looked long and hard on ebay, but found few bargins and few units with the same features. Still, the supply regulator was never designed to adjust the output to precise small values making it somewhat difficult/tedious to adjust. Adding a small rheostat to the test jig may aid for making fine adjustments on the voltage. Another piece of equipment you will need for this test is an amp meter. At first I used a nice small digital meter I found new on ebay for $15 shipping included. It reads amps to a lowest range of 200uA, more than enough precision for the task. For that price get two. Later as I got to making more precision measurements for the determination of diode n and Is I acquired a Keithley 195A bench volt/amp meter with very high input impedance. The DVM is, of course, my trusty Keithley workhorse.

I have received occasional criticism for the simple test jig with the suggestion that proper measurements cannot be taken with the jig as-is. I note that, while the test setup is simple, the instrumentation is high quality and performs the job well. I have had the opportunity to collaborate with Mike Tuggle, comparing our respective measurements. Even my early characteristic curves taken with the small amp meter compare well and provide a good view of the diode and determination of the diode Rs series resistance. The detail n and Is measurements presented here essentially match, though at somewhat less precision, those data from Mike. The reader should have some assurance that the data and measurements found on this page are vetted and reliable.

Easy protocol as follows:

1) Set up the test with the diode and meters clipped to the jig.
2) Adjust the power supply until the reading on the DVM meter is where you plan to measure. Adjust the voltage (DVM readout) in steps from 0 to 1.0 Volt in 0.1 V increments and record the current (Amps) in a spreadsheet.
3) Repeat at each tenth volt recording while the spreadsheet makes a sweet graph.

With this protocol you get a good look at the diode Current to Voltage (I/V) Characteristic out to about 1.5 V or slightly higher, well into the region where series resistance dominates the curve. This curve unfortunately does not communicate much about how well the diode will perform under small signal reception with a crystal radio. For this kind of information one needs to push the simple test jig described above somewhat further, down to low voltage / low current regions where DX level signals predominate. To understand your diode and to better match your diode with the set, the needed information concerns the diode resistance at the zero-crossing point, Ro, or Rd depending on the source of information you are using. The value of Ro cannot be measured directly but may be calculated from I/V measurements at very low currents.

Most probably the single best web article for the measurement of diode Is and n parameters is given by Ben Tongue in his Article 16. In this article he describes an interesting circuit for the measurement as well as protocols for making them. For my purposes I did not wish to make this a construction project and felt I might get along with good quality meters and my already-built "Diode Test Jig". Essentially Ben Tongue's method consists of making two precision measurements of Voltage and Current through a diode at small signal levels, essentially about 3 and 6 times Is (sufficiently low that the voltage drop across the series resistance Ro can be ignored). The measurements are then substituted into the Shockley equation Is*{exp[(qe/(n*k*T))*(V-I*Rs)]-1} and solved simultaneously for the two data pairs. Mike Tuggle has provided a nice excel spreadsheet to do the math. This spreadsheet, Cal_n_Is.xls forms the basis of my technique and I am thus indebted to both Ben Tongue and Mike Tuggle for making this project feasable.

In addition to simply calculating the main parameters Is and n, I also wished to measure enough points to plot a characteristic curve, and to compare the measured curve with one calculated directly from the Shockley equation. My first spreadsheet then combined Tongue/Tuggle calculation protocol and a graphical view of the match between measured and theoretical. I did make a few methodology modifications which I thought/hoped would allow added accuracy:

1) Using the full Shockly equation without simplifying for an assumed 25dC room temperature. While the 25dC assumption is generally good and probably within the measurement error (or perhaps not), including the actual measured temperature eliminates doubts of inaccuracies due to this parameter. With the power of PC's and spreadsheets there is no reason simplify the equation.
2) Used Vd = 0.04 and 0.05 V (adequately close to Ben Tongue's recommended 0.039 and 0.055 V) whenever possible. Note for some diodes with significantly different forward voltage drops, Si diodes in particular I had to use higher values for Vd.
3) Reporting: I decided that, as there is no unique solution to n and Is, each is dependent on the values Vd and Id, I feel that reporting both Vd and Id is necessary for repeatability. Naturally I also include the ambient temperature in the report as well, and
4) I included a calculation for Ro (or Rg if you are using Tongue's reference) as that is the goal of the exercise.
A screen shot shown below:

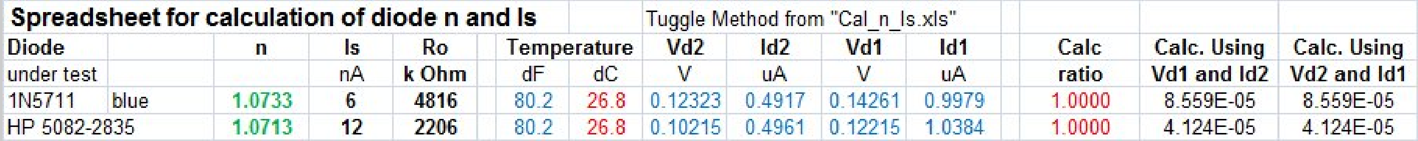
301.4	45	913	1.11	233	

To use the sheet one need only adjust the voltage Vd to that shown in the first column and record the current Id. If only Vd1/Vd2 and Id1/Id2 are measured then the next step is to adjust the value for "n" until the match between the two equations is exact. I even provided a simple ratio calculation to easily test for a match.
While the math is good and results excellent, I quickly found a couple deficiencies in my method,
1) measurements require high precision and its nearly impossible to land EXACTLY at the voltage required. I needed only to get quite close, let the meters stabilize for 2 - 5 minutes, and then record BOTH Vd and Id.
2) the work is rather tedious and, for a large number of diodes it pays dividends to measure only the needed Vd and Id and let the plot aside. My second spreadsheet thus dispenses with the plot. It is with my second spreadsheet that all my data tables and results are posted.
3) better comparisons between diodes can be made if one targets specific Currents rather than Voltages, discussion on this below.

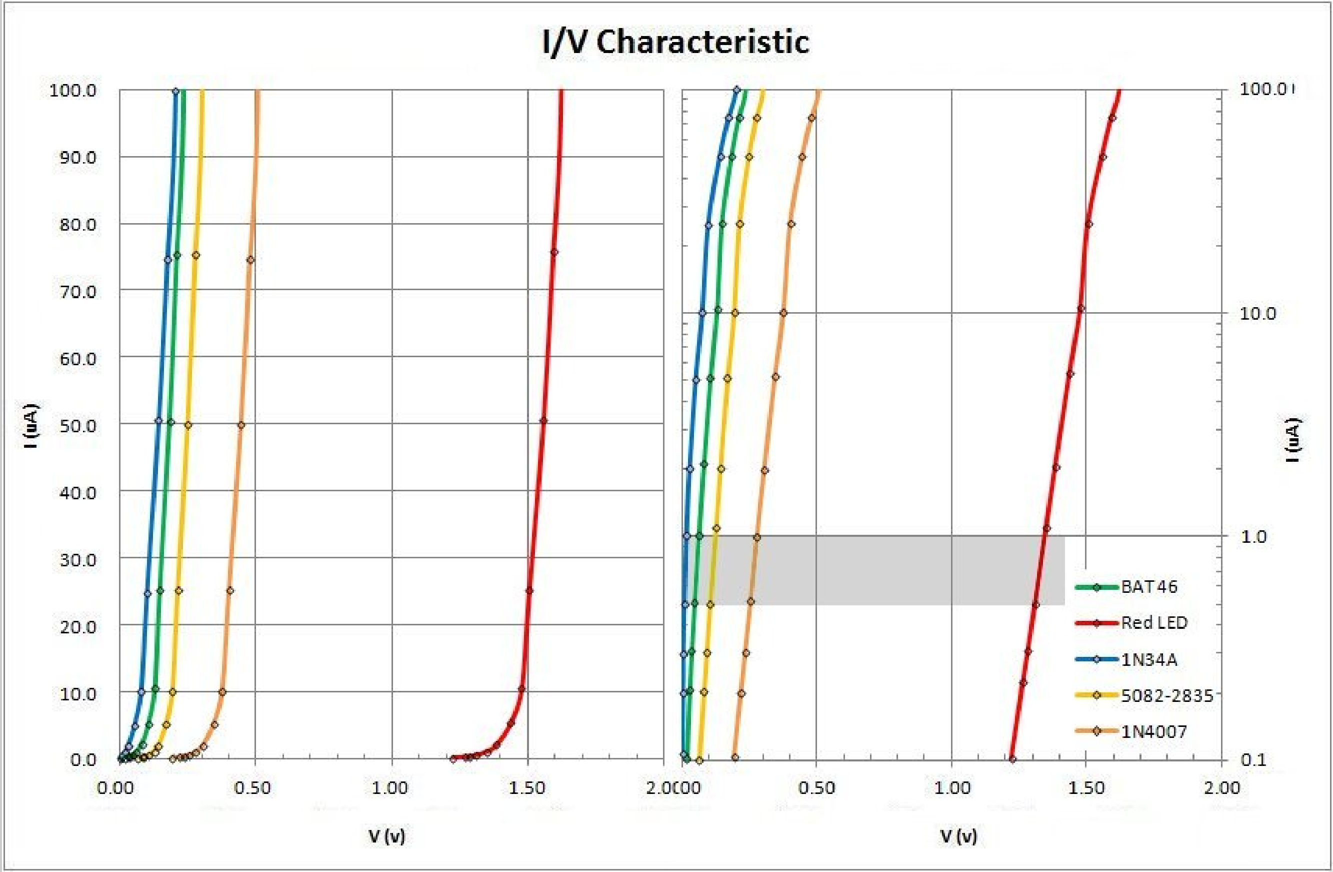
A view of my current data reporting spreadsheet showing ALL input parameters as well as determined values of n, Is, and Ro.
Data input fields in blue: (target Id1 close to 1.0 uA and Id2 close to 0.5 uA).
Calculated fields in red and black.
Adjustment field "n" in green: (adjust value of n until the ratio of the two calculations = exactly 1).



Spreadsheet for calculation of diode n and Is							Tuggle Method from "Cal_n_Is.xls"							
Diode		n	Is	Ro	Temperature		Vd2	Id2	Vd1	Id1		Calc	Calc. Using	Calc. Using
under test			nA	k Ohm	dF	dC	V	uA	V	uA		ratio	Vd1 and Id2	Vd2 and Id1
1N5711	blue	1.0733	6	4816	80.2	26.8	0.12323	0.4917	0.14261	0.9979		1.0000	8.559E-05	8.559E-05
HP 5082-2835		1.0713	12	2206	80.2	26.8	0.10215	0.4961	0.12215	1.0384		1.0000	4.124E-05	4.124E-05

(Note: the engineers in the crowd will have noticed in the above report than I am carrying a degree of precision not justified by the level of accuracy in my measurements. The final results of n, Is, and Ro should be rounded off to not more than three significant figures.)
A copy of my spreadsheet can be downloaded here: Cal_n_Is_Rd.xls

While measuring a good number of diodes, both Germanium, Schottky, Silicon, and even a few LED's, I noted that Tongue's recommended measurements at Vd = 0.039 and 0.055 V resulted in current reports spread out over more than two orders of magnitude. As the determination of Is and n is not unique but a function of Id, I felt uneasy by this method. While most Germanium diodes I have measured have a fairly narrow range of Forward Voltage drops, (Vf), that of Schottky's can range up to a tenth of a volt. This is the factor responsible for the huge range of measured Id values, see the following plot of I/V characteristics for some selected diodes:



In order to get what I feel is a better comparison between diodes, I have decided to target not some pre-determined voltage, but rather target currents of Id = 0.5 and 1.0 uA. On the above plot on the right (with Log Id vs Vd scale) it will be clear that I am aiming at the same part of the characteristic curve regardless of Vf. Hopefully this will allow good comparison between diodes with rather different Vf, even as far as including Silicon and LED's in my mix. Still, on study of the plot above, I must note that the Germanium characteristic at 0.5 to 1.0 uA appears to be curving towards its zero-crossing. Perhaps targeting an amp range between 3.0 and 5.0 uA would have been better, still thinking here, on va voir....

Shockley equation Id = Is*{exp[(qe/(n*k*T))*(V-I*Rs)]-1}
where:
n = ideality factor
Is = Saturation current in Amps
Id = Diode Current in Amps
Vd = Diode Voltage
k = boltzmann = 1.38E-23 J/K
T = temp K = 300
K = dC + 273.15 Kelvin
qe = electron charge = 1.609E-19 cmb

Often simplified to:
Id = Is*(exp(Vd/(0.0256789*n))-1)

Diode Resistance Ro = VT * n / Is
Where:

T = 300K
VT = k*T/qe = 0.0256789
SO: Ro = k * T / qe * n / Is

Ebers-Moll equation Vf = m (kTq) ln [(If / Is) +1]

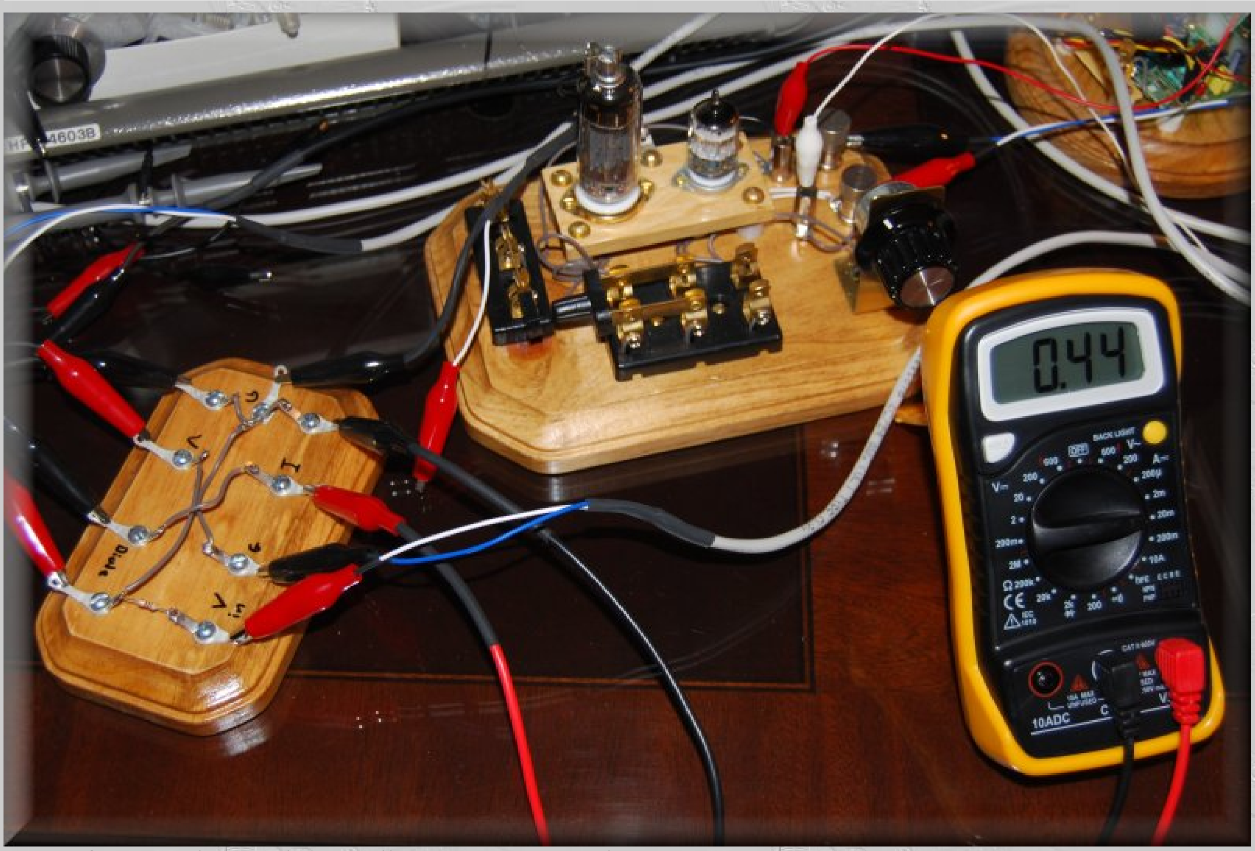


Photo of the lab with my diode test jig, amp meter, and diode vacuum tubes under test.

My radio "laboratory"

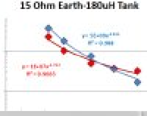
Back to Radio..

Having now acquired several crystal radios by purchase (two) or building my own (four), I begin to wonder how they stack up against each other and against other radios I read about and dream of on the net. It can be fairly common to hear radio performance described in qualitative terms, "high Q", "sharp tuning", "highly sensitive", etc. Without measured numbers to back them up, it is extremely difficult to judge the subjective notes of different radio users. It is inevitable I believe that in this hobby that one ends up getting together as much test equipment as possible, (read "affordable") in order to know more objectively about the radios one builds and/or uses. This page is the tale of my own effort to equip a small "laboratory" of sorts for just such purpose.

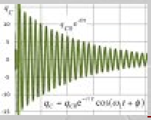
My first needs were related to my building projects and included meters for measuring capacitance and inductance. I have excellent-quality bench meters for other hobby projects including a Keithley 192 and 181 voltmeter with IEEE 488 computer interfaces. These are voltmeters only though, nothing else. My first purchase then was a capacitance/inductance meter. It worked great for capacitance, but the lowest range for inductance, 20mH unfortunately is useless. So, this meter was quickly followed by a stand-alone inductance meter ranging down to 200uH. I use these frequently when making or measuring coils, and measuring capacitors purchased on ebay, better to design a radio around a specific componant.

My next needs follow logically, what about the radios I build?, how do they do? For the non-electrical engineer, testing radios is a bit of a daunting task and this page is by no means intended to be a tutorial. I do give my experiences so that perhaps someone with the same idea may benefit and possibly avoid the mistakes I have certainly made. I describe my equipment and the protocols used in my testing, but I STRONGLY refer the reader to the following two pages for technical guidance and explanations, most of what I do came directly from here:
Dick Kleijer crystal-radio.eu http://www.crystal-radio.eu/enqmeting.htm
Gollum愀 Crystal Receiver World http://home.snafu.de/wumpus/gollum/testing.htm article by C.A. Lauter
I heartily express my appreciation to our European friends for making available on the web these excellent technical tutorials for crystal radio testing.

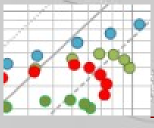
Testing and understanding your set from the Antenna at the front, the tank in the middle and on to the Diode at the back and then the Radio complete, the whole shebang!



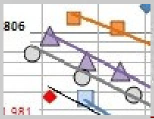
ANTENNA TUNING UNIT.. Design notes and Models, Effect of earth resistivity..



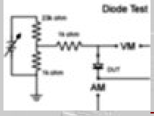
COIL Q.. An Analytical Approach to the measurement of coil Q.



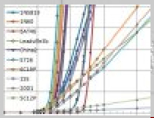
COIL Q Revisited.. Web research and personal measurements: Setting expectations for Q.



Crystal Radio Capacitors.. A look at capacitor Q and its relation to ESR (Equivelant Series Resistance).

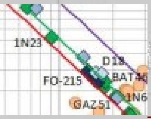


Diode I: Setup and Protocol.. Describes a useful protocol for determination of Diode Is, n, and Ro.

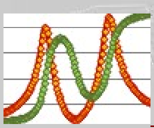


Diode II: Test Data Measurements .. Reports the measurements made under the above protocols for a large variety of diodes

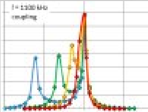
Diode III: Vacuum Diodes.. Measurements and discussion on vacuum diode utility in crystal radio.



Diode IV: Discussion and Results.. A discussion of diode I/V characteristics, Ro and matching, and sundry ravings.



RESONANCE.. A look at some theory and resonance calculations for MW sets.



RADIO TEST.. Describes protocols and results of radio performance testing on my sets.

Conclusion

So, for an investment in a few key pieces of good equipment, yes at some non-trivial cost, you can appreciate the hobby so much more. I have an oscilloscope as well, but so far have not explored its value. I prefer the recording and spreadsheet methods as they give a better record of the results and allow graphing and easy comparison. Knowing how your sets perform, being able to test your diodes, knowing your coil inductance are all important aspects of knowing your radios. I certainly recommend this!
Ciao!

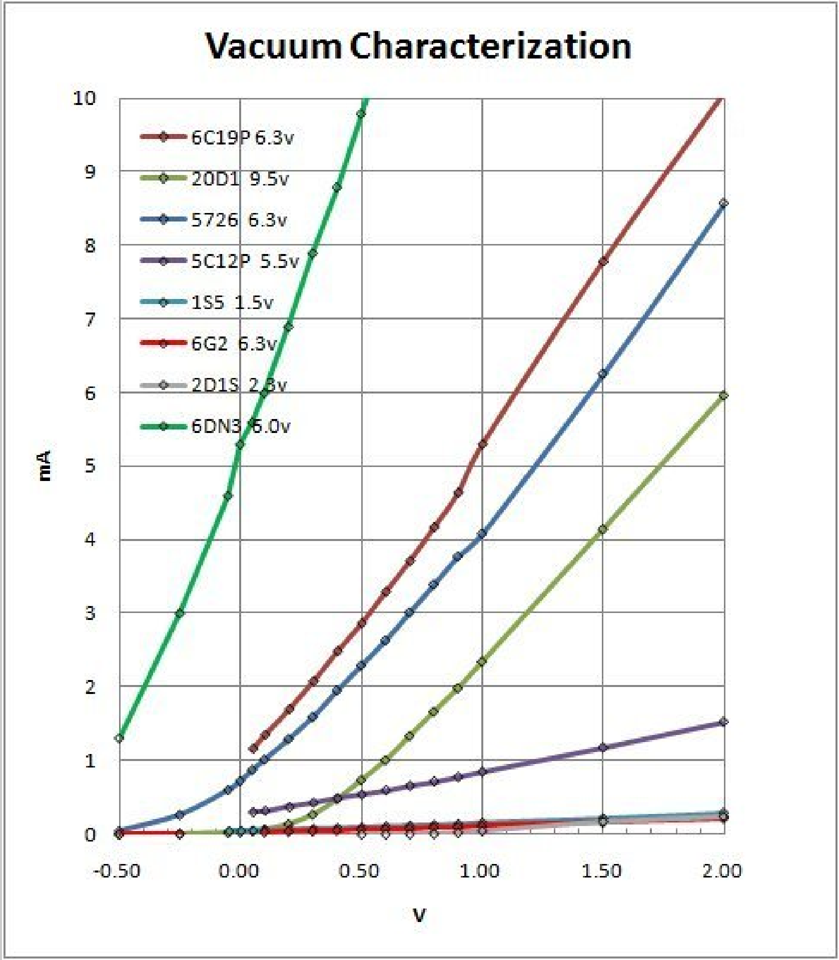
Part III: Vacuum Diode Test Data Report

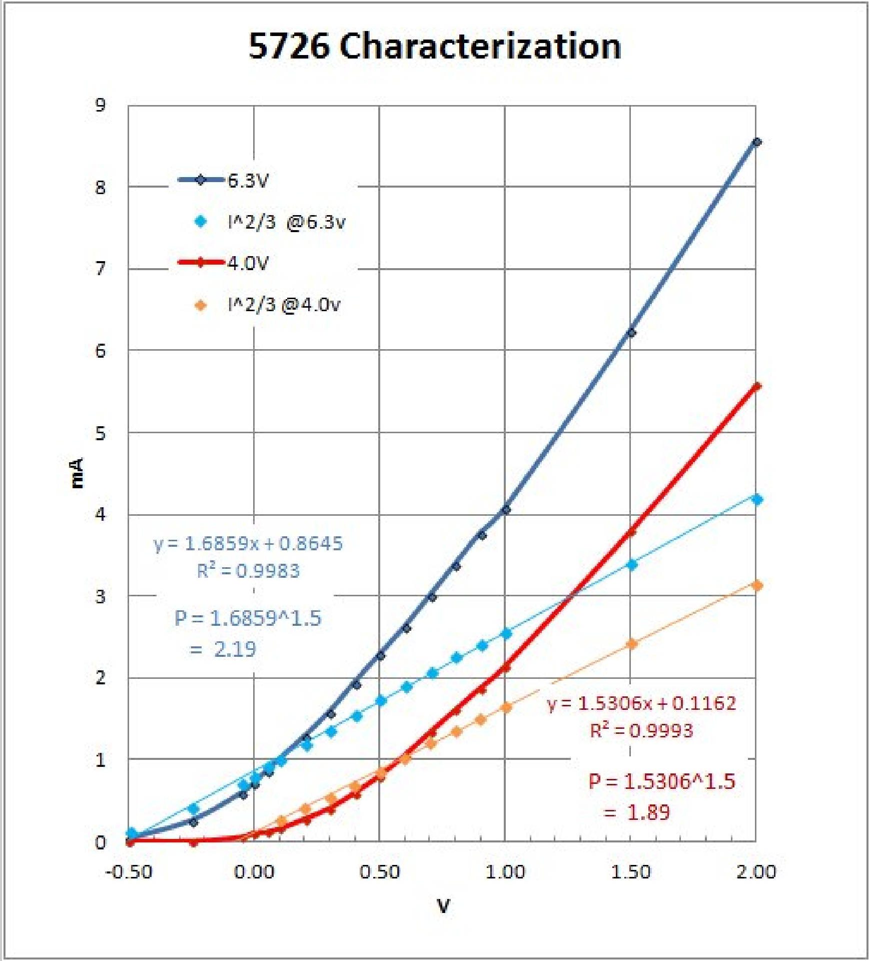
Back to Lab..



When I decided early on to construct a radio based on the vacuum diode (see my Fleming Radio section), I had to find a suitable tube for the project. That began with an extensive search through the datasheets checking vacuum diode properties and reviewing the characteristic curves for a large number of diode tubes. In the above figure I plot the characteristics as best I can on a common plot for comparison. I was hoping to find a good candidate with sensitive characteristics and low energy consumption. As you will find, such a beast did not exist. Following this research began a period ot purchase and testing.

I have tested seven different tube types including 6.3V rectifier diodes that take a lot of power to run and are not really suitable for battery use, a 9v dual diode tube (20D1), a pentode/diode tube (1S5) that is designed to run on a battery at 1.5V and 50mA, and a couple miscellaneous but cute tubes. In testing the 1S5, I found the filament never glowed incandescent at 1.5V and, on measuring, was barely sensitive to anything. I cannot imagine this tube would make much of a diode for crystal radio use. I tested different manufacture 1S5 tubes from two different suppliers. No dice. Finally, I tried to push the tube to operate at higher-than-specified voltages. At 4.3V the I-V curve was still very flat, but shifted slightly higher, crossing the Amp axis at about 0.4 mA, (see graph). At 5.5V one of my tubes gave up the ghost and I didnt do more. I pretty much rule the 1S5 out for my crystal radio work. Looks like i'll be needing the power supply when I get around to building/operating that Fleming Radio.

A question remains as to what in fact is different about these tubes to give such different characteristics. While the I/V characteristic of most vacuum diodes pretty much follow the Langmuir-Child Law, the steepness of the I/V characteristic is largely due to the geometry of the tube elements and the volume of electron space-charge between them. JB Calvert's Theory of Vacuum Tubes informs one that this is the property called Purveance in a vacuum diode. Measuring this requires plotting I raised to the 2/3 power against V and taking the slope of the best-fit line through the data. This slope raised to the 3/2 power is the perveance. The following chart illustrates graphically the relation between the tube characteristic and perveance. For the 5726 tube I plot the characteristic in dark blue for the tube heated with the design 6.3 volts. In light blue I have plotted the measurements and raised them to the 2/3 power. One sees immediately that the new curve is linear. The slope of the curve raised to the 3/2 power yields the perveance factor for the tube.
(Note in addition that when running the tube at a more sensitive point with 4 volts only on the heater the perveance is slightly less than spec.).



With my measurements calculating the perveance is practical and quickly done, results as follows:

Tube	Perveance		R2	
6C19P	2.54		0.997	
5726	2.19		0.998	
6DN3	5.40		0.997	
20D1	2.02	LC?	0.985	(may not follow Langmuir-Child)
5C12P	0.32		0.999	
1S5	0.063		0.999	
2D1S	0.155	LC?	0.975	(may not follow Langmuir-Child)
6G2	0.050		0.999	

The perveance numbers above range from 0.02 to over 2 mA/V^3/2 (with >2 being good for small-signal detection) and clearly shows my choice of the 6C19P to be an excellent one. I am surprised to see a huge 5.4 for the 6DN3 diode, a color television damping diode. It takes a Novar 9-pin socket and is a large tube so doing more with this tube may have to wait a bit.

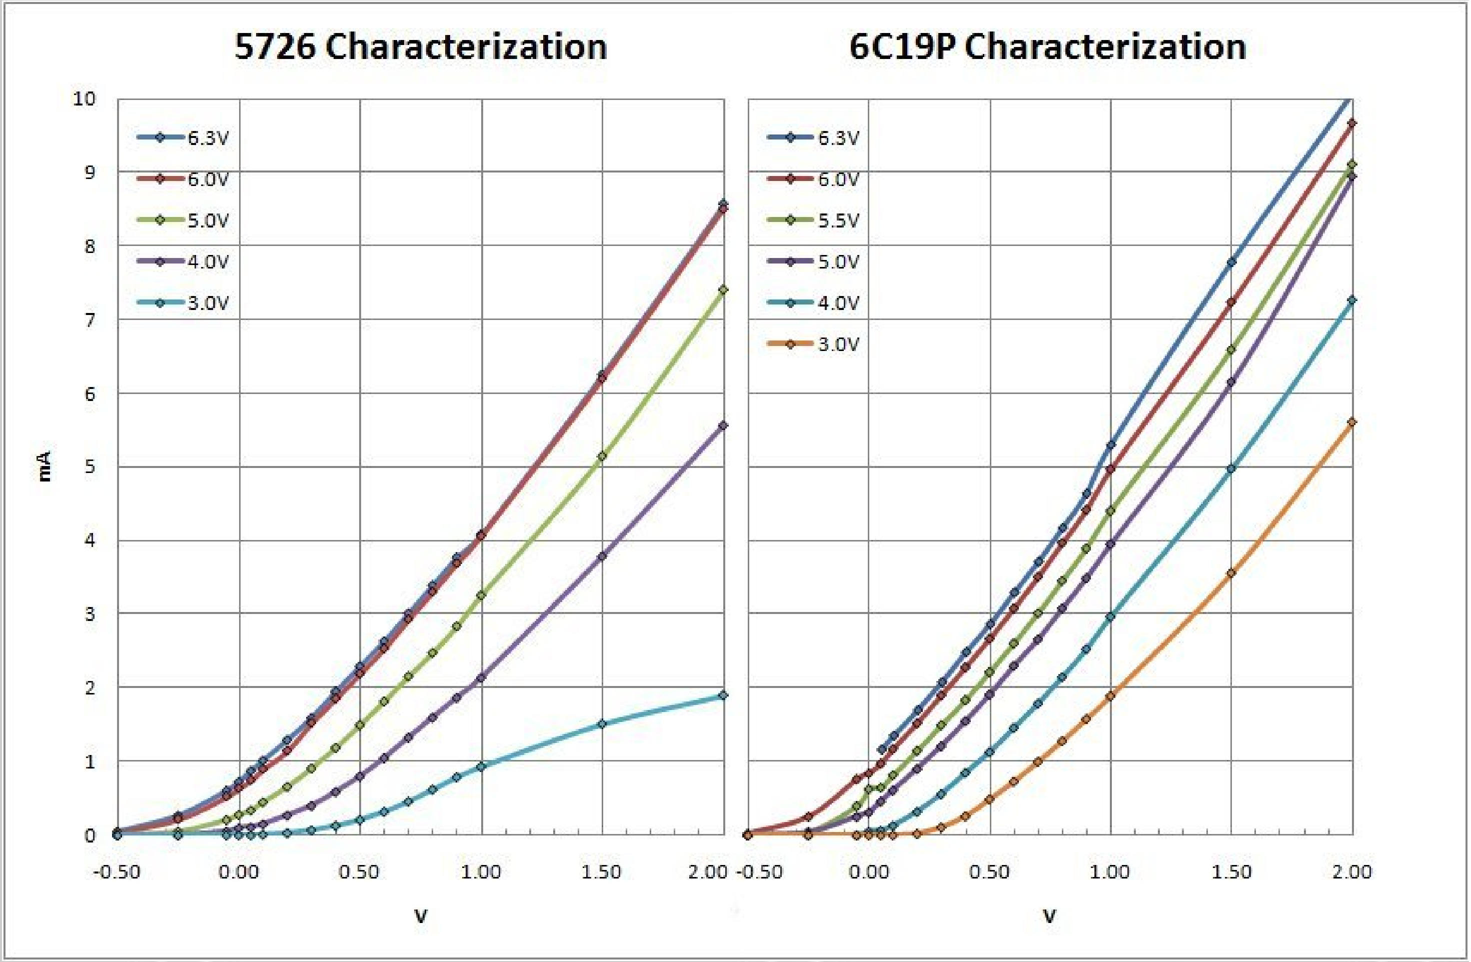
Calvert's 2001 published data

Tube	Perveance
6AL5	2.42
6H6	0.50
7Y4	0.58
2X2A	0.017
6V3-A	2.3
6AX4GT	1.42
6AV6	0.085
1A3	0.075

The high-perveance diode tube types I tested show an interesting property in that their characteristic curves do not pass through the origin of the graph. These curves are wholly acceptable as crystal radio detectors although they will require power to operate. What I have noticed with such tubes is that when I turn them off after using them with a radio, on cooling they go through a period of much increased sensitivity (very loud) before fading to nothing. It is as though running them at the full 6.3V lowers their full potential as crystal radio rectifiers. The reason is in the high perveance of the tubes, the anode

is already proximate to the space charge before any plate voltage is applied. Effectively, while the plate (anode) "Zero" voltage is measured with respect to ground, the plate itself is still positive with respect to the cathodic space charge. Small currents will continue to flow even with a negative bias to the plate, (Contact potential).

In order to explore this idea, I ran a series of tests with the tubes running at lower operating voltages (effectively diminishing the space charge thus lowering the perveance) as shown:



Here you see the impact of lower operating voltages. With the tube operating between 3 and 4 volts the characteristic curves begin to pass through the origin as in regular solid-state diodes and crystals. It is precisely in this voltage range that I found the radio sensitivity, as measured by loudness to my ear, to be most pronounced. The diode characteristic needs to pass through the origin of the I-V graph for rectification at highest sensitivity. This takes me to the 20D1 tube which operates at 9v but only 200mA. This will still take a power supply to use, but the good thing is that the characteristic curve passes through the origin. Running at its design parameters the tube looks a lot like the 6C19P at 4v.

A conceptual look at the impact of heater temperature on the space charge distribution in the annulus between cathode and anode. I start by drawing a qualitative plot of charge density versus distance from the cathode. This is not how such plots are done in the literature but it is a nice visualization. The distribution of charge is a statistical function of heater temperature and plate bias. For the zero-bias case I show qualitative distributions for three heater voltages, 3.0, 4.0, and 6.0 volts. On my chart of current/voltage I find no current flows with 3.0 volts on the heater. Current just begins to be measurable at 4.0V and at 6.0V I found a significant 0.83mA of current indicating that a good portion of the space charge is not impinging on the plate even with zero bias.
Biasing the plate positive will have the effect of "pulling" the space charge towards the plate increasing the current while a negative plate bias will have the opposite effect. With 6.0V heater it will take nearly a negative half volt before the current stops. This is death to sensitivity in a crystal set. Operating the heater at 4.0V provides the most efficient rectification.
Note also that high perveance is not merely a matter of placing the plate as close as possible to the cathode. This may cause an excessive zero-bias current to overcome. The surface-area of both cathode and plate are also critical with large areas providing high current transfer. Vacuum tubes such as pentodes with an included diode plate are poor rectifiers having very low perveance. This is due to the small plate stuck in with all the other hardware in the tube. Get a "fit for purpose" diode for best results.

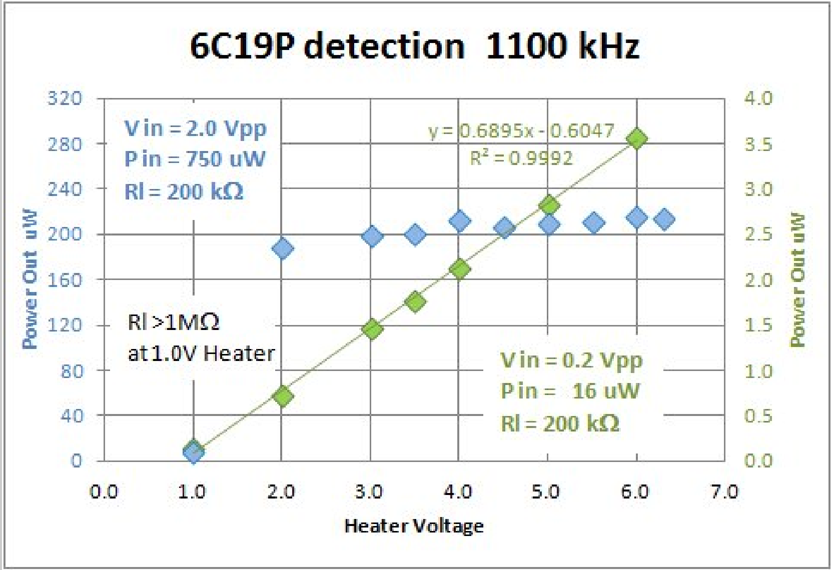
Current across diode at ZERO applied voltage



Note that while the above model as well as hearing (a kind of "hearing is beleiving" thing) supports the 4.0V heater voltage as a sweet spot for highest rectification efficiency, I have yet to be able to measure this. Using my tube-driven Telefunken set (see description on my main radio page) I made a series of output signal power measurements at various tube heater voltages. In this I found no relation between matched output power and the tube heater voltage at 20mV input (2.0Vpp on signal generator), and a monotonic increase in output power at 6mV input (0.2Vpp on the generator). I was seeking a peak output power at around 4.0V on the heater so this result is disturbing. I can hear it, but cannot measure it.

(57) **ABSTRACT**

A method of converting atmospheric electrical discharge to a useable form of energy by arresting, storage and retransmission of lightning induced electrical discharge is disclosed. The invention discloses methods of deploying this technology even in isolated locations where no electricity infrastructure exists. Additionally, the potential for achieving in excess of 1 GWe of electrical power supply at costs orders of magnitude lower than fossil fuel or solar is also disclosed. Isolated collection units are disclosed. A method of deployment of these devices on individual cars and recharge stations is disclosed which in effect unplugs these automotive and recharge stations from the grid. This capability significantly decreases their dependence on the electricity grid infrastructure, enabling a much more enhanced rollout capability for the industry. The concept of Energy Dams is disclosed. These are facilities with substantial electrical energy storage capacities with the capability of receiving energy feeds from various generation sources.

METHOD OF ATMOSPHERIC DISCHARGE ENERGY CONVERSION, STORAGE AND DISTRIBUTION

TECHNICAL FIELD

This invention relates to the field of electrical energy generation and storage in general and the conversion of atmospheric electrical discharge to a useable form of energy by arresting, storage and retransmission of lightning induced electrical discharge in particular.

BACKGROUND OF INVENTION

Lightning has always been a destructive force of nature. Causing death by electrocution and starting fires both in residential areas and in forests. In either case the loss of life and property is substantial. Lightning strikes have affected communication systems, and by uncontrolled arcing, electricity grids leading to loss of power with substantial economic loss

Lightning is the number one cause of forest and farm fires just in the United States and causes over 80 percent of all livestock losses due to accidents. Property losses run into billions of dollars annually and thousands of deaths and injury are reported yearly. Business losses from power and communications failure run into billions of dollars annually. Up to now, lightning strike damage has generally been controlled primarily by grounding.

A lightning discharge can have voltage of 10 MV to 100 MV and current of 1 kA to 300 kA. It packs so much voltage that it can leap a mile through the air and strike another object. Lightning can strike a building directly or leaping to it after striking a tree or other nearby object or by following a power line. It can strike any object that provides an easier path to the ground for it than the air. Because of the large network of lines, lightning can strike a utility pole at one point and be transmitted to any location in the network. Because of this, utility companies use multiple grounding and other protective devices per mile to ameliorate the lightning effects.

There has been a lot of activity in the alleviation of lightning damage but none in utilizing its energy potential.

U.S. Pat. No. 7,495,168 discloses a dipole lightning conductor which can gather electrical charges from the atmosphere during a thunderstorm, opposite to the polarity of the adjacent cloud on one side and induce a different polarity on the other end contacting the ground. When a sufficient potential difference is reached between the dipole and the earth, a dielectric breakdown occurs sending a large amount of earth charge to the thundercloud, inducing a thunderbolt.

In U.S. Pat. No. 6,012,330, Palmer discloses a method of inducing lightning strikes by shooting a stream of ionized water into a thundercloud and triggering electrical conduction through the ionized water column to the ground. In this invention, while ionized water is used, advantage is taken also of capillary wetting of conducting mesh cable at the tip of which is tethered a balloon of conductor coated Mylar. It is easier to float a balloon than to pump a column of water to any significant height.

In U.S. Pat. No. 6,320,119 Gumley discloses a capacitively coupled composite air terminal with sharp and rounded end components for voltage manipulation to minimize electric field ahead of streamers to minimize corona discharge.

Kato, in U.S. Pat. No. 5,280,335, discloses a compound lightning low voltage arrester with high energy tolerance for power and telephone lines comprising a spark gap is connected to a serial combination of Zinc Oxide arrestor and a non-inductive resistor. By cooperative execution between the spark gap and the Zinc Oxide arrester, the Zinc Oxide is chosen to be of a rating such that thermal breakdown does not occur before the spark gap ignition voltage is reached. The arrangement ensures reliable and predictable discharge and arrester survival even under multiple lightning strikes of close proximity.

Subbarao in U.S. Pat. No. 4,338,648, discloses a discharge counter and arrester current meter to determine arrester steady state current and the number of discharge events occurring during a thunder storm lightning arrester event.

Greenwald and Moses in U.S. Pat. No. 5,610,813 disclose a thunderstorm cell detection and mapping system for acquiring localized lightning strike information and identifying and locating active thunderstorm cells.

In U.S. Pat. No. 4,272,720, a method of differentiating between cloud-cloud and cloud-ground discharges is disclosed. Indicating discharge events with no accompanying lightning ground strike. This indicates that even in the absence of streamers, there is significant electrical discharge that can be converted and stored.

Weir and Nelson disclose in U.S. Pat. No. 7,033,406, a high energy density ceramic capacitor with energy capacity of 52 kW·h in 2005 cu·in, the equivalent of 1600 kW·h/m^3. Hansen in U.S. Pat. No. 6,078,494 discloses multilayer ceramic capacitors comprising doped barium-calcium-zirconium-titanate dielectric, the materials basis for U.S. Pat. No. 7,033,406. It is claimed to be characterized by high dielectric constant, high stability of capacitance value, long service life, low loss factor, high insulation resistance capacitance, low voltage dependence, and wide temperature range stability. Electrodes of base metal alloys from the group of Ni, Fe, Co or their alloys are claimed to be perhaps just as effective as noble metals containing gold, silver, platinum and palladium and may also contain Cr, Ti, Zr, V, Al, Zn, Cu, Sn, Pb, Mn, Mo and W.

Although the energy density capacity is not disclosed, it may be in the same range as U.S. Pat. No. 7,033,406 showing a path for storing the energy that can be extracted from lightning discharge.

U.S. Pat. No. 5,361,187, claims dielectric constant (k) of up to 19000 using similar group of dielectrics and processes. In U.S. Pat. No. 5,604,167 dielectric constant values of between 11,000 and 14,000 are disclosed by the same inventor with equivalent materials and processes.

Since these capacitors use standard powder processing technique, it can reasonably be expected that equivalent characteristics may be observed with naturally occurring doped silicates such as phyllosilicates for example, montmorillonite: $(Na,Ca)_{0.33}(Al,Mg)_2(Si_4O_{10})(OH)_2.nH_2O$, or cyclosilicates such as Benitoite—$BaTi(Si_3O_9)$ as base materials appropriately calcined and doped.

In U.S. Pat. No. 6,078,494 multilayer ceramic capacitors comprising doped barium-calcium-zirconium-titanate dielectric is disclosed. It is claimed to be characterized by high dielectric constant, high stability of capacitance value, long service life, low loss factor, high insulation resistance and low voltage dependence, and wide temperature range stability. Electrodes of base metal alloys from the group of Ni, Fe, Co or their alloys are claimed to be perhaps just as effective as noble metals containing gold, silver, platinum and palladium and may also contain Cr, Ti, Zr, V, Al, Zn, Cu, Sn, Pb, Mn, Mo and W. In U.S. Pat. No. 5,361,187, the inventors claim dielectric constants of up to 19000 using similar group of dielectrics and processes. In U.S. Pat. No. 5,604,167 dielectric constant values of between 11,000 and 14,000 is disclosed by the same inventors with equivalent materials and processes. Since these capacitors use standard powder processing technique, it can reasonably be expected that equivalent characteristics may be observed with naturally occurring doped silicates such as phyllosilicates for example, various grades of montmorillonite: $(Na,Ca)_{0.33}(Al,Mg)_2(Si_4O_{10})(OH)_2.nH_2O$, or cyclosilicates such as Benitoite—$BaTi(Si_3O_9)$ as base materials appropriately calcined and doped.

Although the technology to arrest lightning strikes has been around for at least a hundred years, this invention to harness and store that power has only become viable due to recent advances in super-capacitor technology which has made possible the fabrication of ultrahigh capacitance capacitors with very long lifetimes, high power, high energy densities and very fast charge and discharge rates.

Just as flood water, another destructive force of nature in times past was controlled by building dams, and from the dams eventually came hydroelectric power; and wind including thunderstorms has now been harnessed to generate electricity, this invention describes the technology to harness the power of atmospheric discharges including lightening storms to generate useable electrical energy.

This disclosure also introduces the concept of an Energy Dam. Facilities of substantial energy storage capacity capable of receiving energy feeds from various energy sources such as Solar, Wind, Thermal Power plants and Lightning. For example, during a thunderstorm, electricity generated by wind and lightning is collected and stored.

Lightning strikes every part of the globe but not uniformly. The regions with the highest historical concentration of lightning strikes are shown in FIG. **1***c*. These include Florida and the Gulf Coast in the Americas, the Equatorial Highlands of DRC, Rwanda and Burundi in Central Africa and the Monsoon Belt in Asia.

Except for the Americas, typically, these regions have very little electricity infrastructure. With the capability disclosed here, substantial reserves of electricity can be generated, stored and possibly traded.

In regions of epileptic electricity supply, disruptions in power do not necessarily translate into disruption in service. Since when power is generated, it is fed into these energy dams or local storage units for eventual use. Just as in water supply, the customer is not necessarily conscious of when the local water company is pumping water into storage tanks or local dams, in energy dams, the customer need not be conscious of whether or when electricity is being generated by the utility company because the power to his home is drawn not necessarily live from the grid but from the local energy storage units or energy dams.

BRIEF SUMMARY OF THE INVENTION

A method of harnessing atmospheric discharge and storing said energy in a useful form for subsequent use is presented.

Since the voltage of a lighting bolt can be as high as 100 MV, a methodology for safely channeling this discharge for storage is disclosed.

It is the also the object of this invention to present a storage medium in which an energy capacity of 1 MW·h in a volume of under 1 m^3 can be achieved.

It is also a further objective of this invention to show how lightening strikes on tall buildings can be harnessed to provide energy for the building either directly or fed into the grid.

It is also an objective of this invention to present a methodology for harnessing lightening, heretofore a source of power disruptions for electricity grids and converting it into a useable form of energy and feeding it back into the grid.

Since each electricity grid has a lightning suppression unit, a methodology for harnessing the impulse from these units from lightening strikes and feeding it back into the grid is disclosed.

a method of deploying a network of said storage units along a utility grid is also disclosed.

It is also the objective of this invention to disclose a method of modifying the storage units for single building deployment.

A method of deploying said storage units as vehicular charging centers even in locations not readily served by a utility grid is also disclosed.

A method of manipulating the direction and movement of the lightening bolt in open air locations and redirecting them to predetermined collection points is disclosed.

Lightning storms are some of the major causes of wild fires in the world. A method of redirecting the electrical discharges in any given space via a network of polarized and non-polarized collectors is presented. The discharges can be stored, fed into the grid or grounded.

A method for non-spontaneous discharge generation and storage is disclosed. And a method for adapting the methodology for electric automotive deployment is also disclosed.

DETAILED DESCRIPTION OF THE INVENTION

This invention describes a method of harnessing the electrical energy in atmospheric discharges, including, but not limited to lightning, storing said electrical energy and transmitting said energy for use. To this end, as an illustration, the preferred embodiments are represented in the drawings shown in FIGS. **2** to **15**.

Since lightning discharge voltages range from 10 MV to 100 MV with current of 10 kA to 100 kA, the technology challenge will be in mitigating the ultrahigh power which range from 100 GW to in excess of 10,000 GW. Although individual strikes last less than 100 μsec, thunderstorms usually last longer than 30 min. in any cloud formation and location. Indicating that the energy that can be mined from any location in a thunderstorm can run in excess of 50 GW·H. Enough energy for 500,000 homes consuming 1000 kW·h per month. At $100 per 1000 kWh, the revenue equivalent is $5 million per thunderstorm per location.

In solar energy generation, the cost of a 1 MWe rating PV panel is about $1 million. To achieve 1 GWe, the cost implications will be about $1 billion. In fossil fuel plants, the construction cost is approximately $1.3 million per MWe, putting the cost for a 1 GWe at ~$1.3 billion excluding fuel, carbon footprint, and other operating cost. Though thunderstorms are not continuous, with storage capability, the cost basis for an atmospheric discharge energy source will be several orders of magnitude lower than fossil fuel or solar of any architecture.

One embodiment of this invention is depicted in FIG. **2**. Lightning is collected at the air terminals **10**, **20** and transmitted through the conductor **30** to an arrestor **40** and on to the capacitor **50** where the electricity is stored. From which it can be extracted **60** at point of use or transmitted into the grid.

The degree of atmospheric discharge charge collection can be influenced by the metallurgical composition of the collectors. FIG. **3** illustrates the fabrication of the collector with different metals of varying conductivities and atmospheric and electrical stability. In this embodiment, metallurgical compositions for the various segments comprise Ti, Cu, Al. Other metals or their alloys can be used depending on the required properties and the locations of deployment.

In yet another embodiment of the invention as shown in FIG. **4**, a composite collector with opposite polarity air terminals **100**, **110** is used. The air terminals are isolated from each other by an insulator **120**. The negative polarity terminal serves to deflect and manipulate the charge to the positive terminal from which it is conducted to the storage unit **130**.

Another embodiment of the invention is illustrated in FIGS. **5** and **6**. In this representation, negative polarity collectors, **160** deflect the atmospheric discharge so that they do not reach the ground but are deflected for collection at a predetermined terminal **180** of positive polarity and thereafter storage **200**. A plan view representation of this embodiment is shown in FIG. **6**.

It is essential to mitigate the power of the lightning before storage. In one embodiment of this invention, a collection of varistors of various power capacities, linked in series **270**, **280** and **290** are connected in parallel in lines **1** to n, to achieve a desired capability as shown in FIG. **7***a*. The resultant power is stored in the capacitor **300**. An insulator or fuse **305** is placed at the end of the varistor chain to protect the capacitor **300** against over-current. In the event of overstressing, the dielectric or varistor is deformed and the excess current is grounded.

Each component of the power mitigation unit is any of the following configurations as shown in FIG. **7***b*: A ZnO varistor **312** connected in series with a non-inductive resistor **313** and in parallel with a spark gap **311**. The resultant current is further modulated through another ZnO unit **314** and resistor **315**. A cascade of this configuration could be adopted to achieve the desired properties.

Zinc Oxide has a relatively large band gap of ~3.3 eV at room temperature. The consequence of this large band gap includes, higher breakdown voltages, ability to sustain large electric field and high power and temperature operation. Because of this, ZnO is the primary component in varistors and in voltage suppression devices. Zinc Sulfide has a band gap of 3.5 eV for the cubic form and as high as 3.91 eV for the hexagonal form at 300K. While ZnO band gap can be tuned from between 3-4 eV by alloying with magnesium oxide or cadmium oxide, the co-processing of ZnO with ZnS of the hexagonal wurtzite form should provide electrical field and other operational advantages over ZnO alone.

Multilayers of ZnO and ZnS or as sandwich layers with each other with ZnO achieving 50-99.9 mol. % of each layer can be adopted to improve on the suppression properties of the single layer ZnO varistor as is shown in FIG. **7***c*. Said varistor comprising a ceramic base body **318** of multiple layers, terminal electrodes **316**, **317** and internal electrodes **319**.

Alloying of ZnO with metal oxides and nitrides of transition elements including W, Zr, Mo, Mg, Cr, and Ti may improve its band gap characteristics and improve its voltage response non-linearity. Tungsten, in the form of tungsten silicide has very unique crystallization characteristics, particularly in the presence of dopants such as phosphorus or arsenic. Upon post deposition anneal, the Si in the non-stoichiometric tungsten silicide (WSix) segregates to the grain boundaries and the film interfaces. The dopant atoms diffuse preferentially along the grain boundaries. When oxidized, it is the segregated silicon that is oxidized selectively. If the W is exposed to the oxidizing ambient of O_2/Ar or O_2/N_2 at temperatures in excess of 700° C., tungsten oxide WOx (x=3, or 1.5) is formed. It has no corresponding crystallographic orientation to the underlying tungsten silicide or metal, being in the form of an amorphous powder. The fabrication of multilayer varistors with ZnO and WSi_2/WO_3, SiO_2 should provide the flexibility of modulation of the effective grain sizes of the host material to within 0.5-10μ as the case may be. This precise grain size control provides corresponding modulation of the electrical properties including overvoltage suppression.

A schematic of the storage unit **320** is shown in FIG. **8***a*. A collection of capacitors **330** are connected in parallel to achieve a desired capacitance. A schematic of the cross-section of each capacitor unit is shown in FIG. **8***b*. The unit **331** with dielectric layers **332** is a multilayer capacitor comprising alternately stacked internal electrodes **335**, **336** connected to external electrodes **333**, **334**. The dielectric layers may be of uniform composition, or layers of different compositions optimized for flexibility in the modulation of desired electrical, physical and reliability properties.

Capacitance in excess of 1 kF/m^3 with energy storage capacity of 1.5 MW·h is reported as being possible by existing art. With compositional and manufacturing improvements disclosed here these benchmarks are expected to be surpassed making possible energy storage capacities of up to 1 GW·h. Sufficient energy for 1000 households consuming 1000 kW·h of electricity per month for one month.

Lightning storms are a major cause of wildfire. To address this, in yet another embodiment of this invention as represented in FIG. **9**, air terminals **360** are set up on a selection of trees and connected by a conductor **370** in a mesh array as shown in FIG. **10**. The impinging charge is transmitted through a conductor **380**, through a suppressor unit **390** and on to the storage unit **400**.

Utility transmission lines usually have lightning collectors along the length of the network. In this invention as demonstrated in FIG. **11** air terminals **440** deployed transmission poles **450** are linked by a polarized conductor **460**. At predetermined locations the impinging charge is conducted through a suppression unit **490** and thereafter into the storage unit **500**. The stored energy is periodically released into the grid.

In yet another embodiment of the invention, air terminals **510** are deployed on light poles **520**. The collected charged are modified and stored in a storage unit **540**.

In another embodiment, the air terminal/collection units are deployed on radio transmission towers. The charge could be stored individually at each tower location or linked in a network as shown in FIG. **13**. In either case, the stored energy be used at each individual location or fed into the grid **570**.

In the absence of a thundercloud, lightening flash can be generated by the modification of the natural bias between the cloud and ground. This is demonstrated in FIG. **14**, where a positively biased conductor **580** of height greater than nearest ground elevation or nearest structure. The increased elevation and bias facilitates cloud to ground discharge even when there is no active lightning storm. The incoming charge is isolated by an insulator **600** and stored in the storage unit **610**.

In yet another embodiment of this invention, a balloon of conductive material is tethered to a terminal via a mesh line of conducting material. The balloon captures cloud to cloud discharges which are transmitted down to storage. In yet another embodiment this tether line may be wetted by a conductive solution such as but not limited to salt solution to facilitate the discharge conduction.

Another embodiment of this invention is shown in FIG. **15**. In an isolated collection system as shown here, the air terminal **620** which may be biased or unbiased is connected to a collection/storage unit **650**, **660** respectively by conductor **640** and isolated by a dielectric or insulator **670**. Should the discharge exceed the capacity of the isolation, the isolation is bridged and the charge grounded. This isolated collection system is particularly useful where there is no utility grid, particularly in very remote and isolated locations.

This isolated collection capability enables deployment on individual houses and isolated farms. In electric automotive recharge stations, this capability enables the location of these facilities in any location even those not served by regular electricity utilities lines.

In isolated rural areas, the deployment of these isolated collection units enables the provision of electricity where electricity grid infrastructure is not available or practical. The storage units can be deployed in banks as the estimated anticipated usage dictates.

In another embodiment of this invention, the isolated collection unit is modified to be portable for deployment on automobiles. The charge in the storage unit is linked with the automobile's electrical power or storage unit. Alternatively, it can replace the power storage unit of the automobile for pure EV or hybrid cars. Additionally, it can unplug these cars from the grid. With the ambitious industry plans for electric or hybrid cars the infrastructure for charging these cars either in garages or charging stations is somewhat limited. The capability to both 'charge as you go' and unplug from the grid would expand the infrastructure significantly.

In yet another embodiment of this invention, the isolated collection unit is deployed on trains. This could be in commuter trains that directly fed from the grid, or long-haul trains to augment or replace the fossil fuel used.

It is understood that the presentation of these steps in this disclosure is not exhaustive. Only the preferred embodiments of the invention and but a few of the examples of its versatility are shown and described in the present disclosure. It should be readily apparent to those of ordinary skill in the art that the invention is capable of use in various other combinations, environments and applications and is capable of changes or modifications within the scope of the inventive concept as expressed herein. These changes and modifications may be made without departing from the spirit and scope of the invention as set forth in the appended claims.

The invention claimed is:

1. A method of converting an atmospheric electrical discharge into a

useable form of electrical energy comprising

deflecting the discharge to an air terminal via one or more separate air terminals of a polarity, the air terminal having an opposite polarity to the polarity of the separate air terminals;

arresting the discharge via the air terminal to a power mitigating (step down) unit via a conducting unit connected to the air terminal; wherein said power mitigating unit is not a transformer,

reducing voltage of the discharge via the power mitigating unit modulated according to a capacity of the power mitigating unit, wherein the discharge is grounded if in excess of the capacity, and wherein the power mitigating unit reduces the voltage of the discharge from approximately higher than 100 MV (mega volt) and 100 kA (kilo amperes) to below 20 kV (kilo volt), 10 kA; and

storing the discharge with the reduced voltage in an energy storage unit connected to the power mitigating unit, the storage unit comprising modules of high energy density capacitors and the storage unit discharging the electrical energy into a power grid or to an appliance.

2. The method of claim **1** wherein the discharge is caused by incident lightning and wherein the arrestor and mitigating unit comprise an array of self-healing varistors in series and parallel chosen to ensure total conversion of the discharge to a voltage/current level suitable for storage in said capacitors.

3. The method of claim **1**, where the power mitigation unit a configuration selected from a group consisting of:

(a) single ZnO varistor,

(b) Zinc Oxide arrester connected in series with a non-inductive resistor,

(c) Zinc Oxide arrester in series with a non-inductive resistor and in parallel with a spark gap, and

(d) a cascade of configurations as described in (c).

4. The method of claim **1** wherein the storage unit comprises modular array of high energy density multilayered doped ceramic capacitors with storage capacity of 10 kW·h (kilowatt hour) to 1 GW·h (gigawatt hour) and volume 0.1 to 1 m^3 and up to 1000 units.

5. The method of claim **1** in which the air terminal and the storage unit are configured in a mobile unit and deployed on mobile platform having a battery, wherein the mobile unit provides the electrical energy to power the battery without a need for recharging the battery at fixed charging locations.

6. The method of claim **1** wherein the storage unit is located in a charging station, and wherein the storage unit includes modular capacitors for charging an electric vehicle from the charging station.

7. The method of claim **1** wherein the air terminals are deployed on buildings, wherein a portion of the electrical energy stored is used by the buildings and wherein a portion of electrical energy is stored in a central energy storage facility connected to a plurality of storage units.

8. The method of claim **1** wherein the said storage units are located underground.

9. The method of claim **1** wherein the storage unit is receives energy feeds from more than one electricity generation sources, each source being selected from a group consisting of Thermal energy source, Hydro energy source, Solar energy source, Wind energy source and Lightning energy source.

10. The method of claim **4** wherein the ceramic capacitors are fabricated to provide modulation of effective grain sizes within a specified range.

11. The method of claim **4** wherein the multilayer ceramic capacitors comprises dielectric layers of varying compositions individually or as sandwich layers with each other containing Barium-Titanate silicates as host material doped with Zr, WSi_2/WO_3 to modulate grain growth to between 0.1 to 10 μm, said modulation providing corresponding control of electrical and reliability properties.

12. The method of claim **2** wherein the varistors comprise multilayers of ZnO and ZnS individually layered or as sandwich layers with each other with ZnO achieving 50-99.9% of each layer, said layers being alloyed metal oxides of transition elements to improve voltage response non-linearity.

13. A method to protect a position from impact of an electrical

discharge caused by lightning, the method comprises redirecting the electrical discharge from the position via an array of air terminals to an air terminal of a collection unit, said collection unit comprising a power mitigating unit and a storage unit and wherein the power mitigating unit is not a transformer, the air terminal of the collection unit biased with a first

polarity, each of the array of air terminals biased with a second polarity with a magnitude, the second polarity opposite to the first polarity, wherein the redirection is controlled by the magnitude and the second polarity; and

storing the electrical discharge in the collection unit located significantly removed from the impact position.

14. The method of claim **13** wherein the discharge redirection is via a biased conductor to the collection unit.

15. The method of claim **13** wherein the position is located in an area of a forest, wherein the array of air terminals are deployed on trees in the forest, wherein tips of the array of air terminals are positioned in close proximity to treetops of the trees, and wherein the discharge is fed into an electricity grid as electrical energy from the collection unit.

16. The method of claim **1** wherein the storage unit is connected to electrical power lines of the power grid and wherein the electrical energy is fed back into the power grid via the electrical power lines.

17. The method of claim **1** wherein the storage unit is located at a telecom tower, a light poles or other free standing structure with a need for operational energy and wherein the electrical energy from the storage unit is used for the operational energy.

18. A method of generation of atmospheric discharge, the method comprising:

modulating bias of a dipole air terminal conductor to capture charges from clouds to ground without occurrence of natural lightning, the conductor including a balloon, a terminal and a tether line connecting the balloon and the terminal, wherein the bias has a magnitude and a polarity controlled by the modulation relative to the ground; and wherein the tether line is a conductive cable soaked by an ionic liquid including salt solution to facilitate conduction of the charge, and

storing the charge in a collection unit comprising a power mitigation unit and a storage unit wherein said power mitigation unit is not a transformer, feeding said charge into an electricity grid or appliance.

* * * * *

A lightning flash to a 23-foot-tall European ash tree near Lugano, Switzerland. The tree suffered no external damage. Photograph was taken from a distance of about 200 feet by Richard E. Orville, State University of New York at Albany, using Kodachrome II 35 mm daylight film, a lens setting of f/5.6, and the shutter on time exposure. (Reproduced in color on front cover.) Additional details are found in Orville, R. E., Photograph of a Close Lightning Flash, *Science, 162,* 666-667, 1968. Lightning photography is discussed in Chapter 10; lightning damage to trees in Chapter 5.

Microwaves

Microwaves are the highest-frequency electromagnetic waves that can be produced by currents in macroscopic circuits and devices. Microwave frequencies range from about 10^9Hz to nearly 10^{12}Hz. Their high frequencies correspond to short wavelengths compared with other radio waves—hence the name “microwave.” Microwaves also occur naturally as the cosmic background radiation left over from the origin of the universe. Along with other ranges of electromagnetic waves, they are part of the radiation that any object above absolute zero emits and absorbs because of **thermal agitation**, that is, from the thermal motion of its atoms and molecules.

Most satellite-transmitted information is carried on **microwaves**. **Radar** is a common application of microwaves. By detecting and timing microwave echoes, **radar** systems can determine the distance to objects as diverse as clouds, aircraft, or even the surface of Venus.

Microwaves of 2.45 GHz are commonly used in microwave ovens. The electrons in a water molecule tend to remain closer to the oxygen nucleus than the hydrogen nuclei (Figure). This creates two separated centers of equal and opposite charges, giving the molecule a dipole moment (see Electric Field). The oscillating electric field of the microwaves inside the oven exerts a torque that tends to align each molecule first in one direction and then in the other, with the motion of each molecule coupled to others around it. This pumps energy into the continual thermal motion of the water to heat the food. The plate under the food contains no water, and remains relatively unheated.

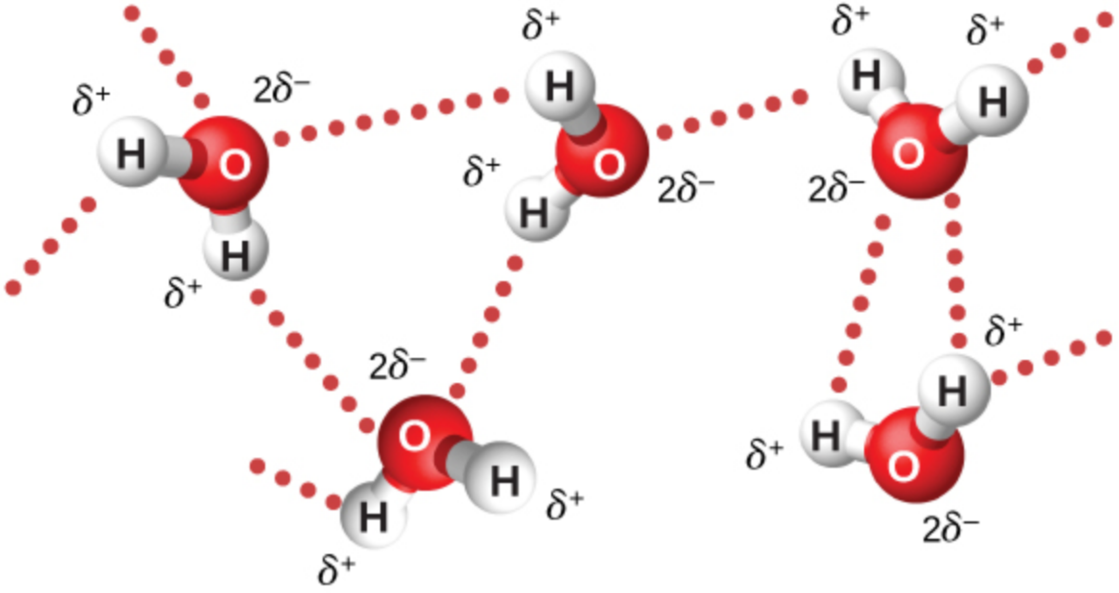

Figure 3. The oscillating electric field in a microwave oven exerts a torque on water molecules because of their dipole moment, and the torque reverses direction 4.90×10^9 times per second. Interactions between the molecules distributes the energy being pumped into them. The δ^+ and δ^- denote the charge distribution on the molecules.

Infrared Radiation

The boundary between the microwave and infrared regions of the electromagnetic spectrum is not well defined (see Figure). **Infrared radiation** is generally produced by thermal motion, and the vibration and rotation of atoms and molecules. Electronic transitions in atoms and molecules can also produce **infrared radiation**. About half of the solar energy arriving at Earth is in the infrared region, with most of the rest in the visible part of the spectrum. About 23% of the solar energy is absorbed in the atmosphere, about 48% is absorbed at Earth's surface, and about 29% is reflected back into space.[1]

The range of infrared frequencies extends up to the lower limit of visible light, just below red. In fact, infrared means "below red." Water molecules rotate and vibrate particularly well at infrared frequencies. Reconnaissance satellites can detect buildings, vehicles, and even individual humans by their infrared emissions, whose power radiation is proportional to the fourth power of the absolute temperature. More mundanely, we use infrared lamps, including those called *quartz heaters*, to preferentially warm us because we absorb infrared better than our surroundings.

The familiar handheld "remotes" for changing channels and settings on television sets often transmit their signal by modulating an infrared beam. If you try to use a TV remote without the infrared emitter being in direct line of sight with the infrared detector, you may find the television not responding. Some remotes use Bluetooth instead and reduce this annoyance.

Radio Waves

The term **radio waves** refers to electromagnetic radiation with wavelengths greater than about 0.1 m. Radio waves are commonly used for audio communications (i.e., for radios), but the term is used for electromagnetic waves in this range regardless of their application. Radio waves typically result from an alternating current in the wires of a broadcast antenna. They cover a very broad wavelength range and are divided into many subranges, including microwaves, electromagnetic waves used for AM and FM radio, cellular telephones, and TV signals.

There is no lowest frequency of radio waves, but ELF waves, or “extremely low frequency” are among the lowest frequencies commonly encountered, from 3 Hz to 3 kHz. The accelerating charge in the ac currents of electrical power lines produce electromagnetic waves in this range. ELF waves are able to penetrate sea water, which strongly absorbs electromagnetic waves of higher frequency, and therefore are useful for submarine communications.

In order to use an electromagnetic wave to transmit information, the amplitude, frequency, or phase of the wave is *modulated*, or varied in a controlled way that encodes the intended information into the wave. In AM radio transmission, the amplitude of the wave is modulated to mimic the vibrations of the sound being conveyed. Fourier’s theorem implies that the modulated AM wave amounts to a superposition of waves covering some narrow frequency range. Each AM station is assigned a specific carrier frequency that, by international agreement, is allowed to vary by $\pm 5\ \mathrm{kHz}$. In FM radio transmission, the frequency of the wave is modulated to carry this information, as illustrated in Figure, and the frequency of each station is allowed to use 100 kHz on each side of its carrier frequency. The electromagnetic wave produces a current in a receiving antenna, and the radio or television processes the signal to produce the sound and any image. The higher the frequency of the radio wave used to carry the data, the greater the detailed variation of the wave that can be carried by modulating it over each time unit, and the more data that can be transmitted per unit of time. The assigned frequencies for AM broadcasting are 540 to 1600 kHz, and for FM are 88 MHz to108 MHz.

Ultraviolet Radiation

Ultraviolet means “above violet.” The electromagnetic frequencies of **ultraviolet radiation (UV)** extend upward from violet, the highest-frequency visible light. The highest-frequency ultraviolet overlaps with the lowest-frequency X-rays. The wavelengths of ultraviolet extend from 400 nm down to about 10 nm at its highest frequencies. Ultraviolet is produced by atomic and molecular motions and electronic transitions.

UV radiation from the Sun is broadly subdivided into three wavelength ranges: UV-A (320–400 nm) is the lowest frequency, then UV-B (290–320 nm) and UV-C (220–290 nm). Most UV-B and all UV-C are absorbed by ozone (O_3) molecules in the upper atmosphere. Consequently, 99% of the solar UV radiation reaching Earth’s surface is UV-A.

Sunburn is caused by large exposures to UV-B and UV-C, and repeated exposure can increase the likelihood of skin cancer. The tanning response is a defense mechanism in which the body produces pigments in inert skin layers to reduce exposure of the living cells below.

As examined in a later chapter, the shorter the wavelength of light, the greater the energy change of an atom or molecule that absorbs the light in an electronic transition. This makes short-wavelength ultraviolet light damaging to living cells. It also explains why ultraviolet radiation is better able than visible light to cause some materials to glow, or *fluoresce*.

Besides the adverse effects of ultraviolet radiation, there are also benefits of exposure in nature and uses in technology. Vitamin D production in the skin results from exposure to UV-B radiation, generally from sunlight. Several studies suggest vitamin D deficiency is associated with the development of a range of cancers (prostate, breast, colon), as well as osteoporosis. Low-intensity ultraviolet has applications such as providing the energy to cause certain dyes to fluoresce and emit visible light, for example, in printed money to display hidden watermarks as counterfeit protection.

X-Rays

X-rays have wavelengths from about $10^{-8}\text{m to }10^{-12}\text{m}$. They have shorter wavelengths, and higher frequencies, than ultraviolet, so that the energy they transfer at an atomic level is greater. As a result, X-rays have adverse effects on living cells similar to those of ultraviolet radiation, but they are more penetrating. Cancer and genetic defects can be induced by X-rays. Because of their effect on rapidly dividing cells, X-rays can also be used to treat and even cure cancer.

The widest use of X-rays is for imaging objects that are opaque to visible light, such as the human body or aircraft parts. In humans, the risk of cell damage is weighed carefully against the benefit of the diagnostic information obtained.

Gamma Rays

Soon after nuclear radioactivity was first detected in 1896, it was found that at least three distinct types of radiation were being emitted, and these were designated as alpha, beta, and gamma rays. The most penetrating nuclear radiation, the **gamma ray (γ ray)**, was later found to be an extremely high-frequency electromagnetic wave.

The lower end of the γ- ray frequency range overlaps the upper end of the X-ray range. Gamma rays have characteristics identical to X-rays of the same frequency—they differ only in source. The name “gamma rays” is generally used for electromagnetic radiation emitted by a nucleus, while X-rays are generally produced by bombarding a target with energetic electrons in an X-ray tube. At higher frequencies, γ rays are more penetrating and more damaging to living tissue. They have many of the same uses as X-rays, including cancer therapy. Gamma radiation from radioactive materials is used in nuclear medicine.

Are radio waves completely different physical objects than gamma-rays? They are produced in different processes and are detected in different ways, but they are not fundamentally different. Radio waves, gamma-rays, visible light, and all the other parts of the electromagnetic spectrum are electromagnetic radiation.

Electromagnetic radiation can be described in terms of a stream of mass-less particles, called photons, each traveling in a wave-like pattern at the speed of light. Each photon contains a certain amount of energy. The different types of radiation are defined by the the amount of energy found in the photons. Radio waves have photons with low energies, microwave photons have a little more energy than radio waves, infrared photons have still more, then visible, ultraviolet, X-rays, and, the most energetic of all, gamma-rays.

Measuring electromagnetic radiation

Electromagnetic radiation can be expressed in terms of energy, wavelength, or frequency. Frequency is measured in cycles per second, or Hertz. Wavelength is measured in meters. Energy is measured in electron volts. Each of these three quantities for describing EM radiation are related to each other in a precise mathematical way. But why have three ways of describing things, each with a different set of physical units?

lower energy

Comparison of wavelength, frequency and energy for the electromagnetic spectrum. (Credit: NASA's Imagine the Universe)

The short answer is that scientists don't like to use numbers any bigger or smaller than they have to. It is much easier to say or write "two kilometers" than "two thousand meters." Generally, scientists use whatever units are easiest for the type of EM radiation they work with.

Astronomers who study radio waves tend to use wavelengths or frequencies. Most of the radio part of the EM spectrum falls in the range from about 1 cm to 1 km, which is 30 gigahertz (GHz) to 300 kilohertz (kHz) in frequencies. The radio is a very broad part of the EM spectrum.

Infrared and optical astronomers generally use wavelength. Infrared astronomers use microns (millionths of a meter) for wavelengths, so their part of the EM spectrum falls in the range of 1 to 100 microns. Optical astronomers use both angstroms (0.00000001 cm, or 10^{-8} cm) and nanometers (0.0000001 cm, or 10^{-7} cm). Using nanometers, violet, blue, green, yellow, orange, and red light have wavelengths between 400 and 700 nanometers. (This range is just a tiny part of the entire EM spectrum, so the light our eyes can see is just a little fraction of all the EM radiation around us.)

chapter one

Why Did Benjamin Franklin Fly the Kite?

Shuffle across a nylon rug on a dry winter day and your body acquires an excess electrical charge. That charge may be violently released by a spark jumping from your finger tip to a light switch or doorknob. Lightning is nothing more than a very long spark which discharges regions of excess electrical charge developed in thunderclouds. Frictional charging, that is charging by rubbing together certain dissimilar materials such as a shoe sole and the rug, has probably always been familiar to man. In 1746 Benjamin Franklin began his experiments in electricity. His experiments were made possible by (1) the frictional charging mechanism and (2) the fortuitous invention earlier that year of the Leyden jar – a primitive capacitor to store electrical charge.

Prior to Franklin's interest with electricity, a number of scientists had suggested that lightning might be an electrical phenomenon. Their concern, however, had gone no further than suggestion. In November 1749 Franklin wrote the following about the sparks (in his terminology, electrical fluid) he had studied.

> Electrical fluid agrees with lightning in these particulars. 1. Giving light. 2. Colour of the light. 3. Crooked direction. 4. Swift motion. 5. Being conducted by metals. 6. Crack or noise in exploding. 7. Subsisting in water or ice. 8. Rending bodies as it passes through. 9. Destroying animals. 10. Melting metals. 11. Firing inflammable substances. 12. Sulphureous smell. The electrical fluid is attracted by points. We do not know whether this property is in lightning. But since they agree in all particulars wherein we can already compare them, is it not possible they agree likewise in this? Let the experiment be made. (Ref. 1.1)

Franklin was the first to design an experiment to prove that lightning was electrical. In July 1750 he wrote:

> To determine the question whether the clouds that contain lightning are electrified or not, I would propose an experiment to be tried where it may be done conveniently. On the top of some high tower or steeple place a kind of sentry box . . . big enough to contain a man and an electrical stand [an insulator]. From the middle of the stand let an iron rod rise and pass bending out of the door, and then upright twenty or thirty feet, pointed very sharp at the end. If the electrical stand be kept clean and dry, a man standing on it when such clouds are passing low might be electrified and afford sparks, the rod drawing fire to him from the cloud. If any danger to the man should be apprehended (though I think there would be none), let him stand on the floor of his box and now and then bring near to the rod the loop of a wire that has one end fastened to the leads, he holding it by a wax handle; so the sparks, if the rod is electrified, will strike from the rod to the wire and not affect him. (Ref. 1.2)

His experiment and the results he expected to achieve are illustrated in Fig. 1.1. The aim was to show that the clouds were electrically charged, for if this were the case, it followed that lightning was also electrical. Franklin did not appreciate

the danger involved in his experiment. If the iron rod were directly struck by lightning, the experimenter would almost certainly be killed. Such was eventually to be the case as we shall see.

In France in May 1752 Thomas-Francois D'Alibard successfully performed Franklin's suggested experiment. Sparks were observed to jump from the iron rod during a thunderstorm. It was proved that thunderclouds contain electrical charge. Soon after, the experiment was successfully repeated in France again, in England, and in Belgium. In July 1753 G. W. Richmann, a Swedish physicist working in

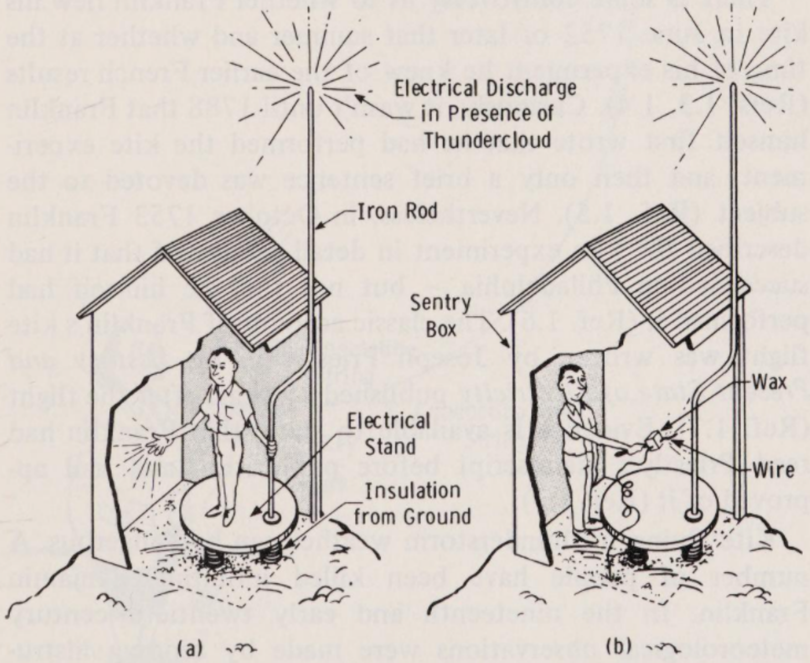

Fig. 1.1. Franklin's original experiment to show that thunderclouds are electrified. (a) Man on electrical stand holds iron rod with one hand and obtains an electrical discharge between the other hand and ground. (b) Man on ground draws sparks between iron rod and a grounded wire held by an insulating wax handle.

Russia, put up an experimental rod and was killed by a direct lightning strike.

Before Franklin himself got around to performing the experiment, he thought of a better way of proving his theory – an electrical kite. It was to take the place of the iron rod, since it could reach a greater elevation than the rod and could be flown anywhere. During a thunderstorm in 1752 Franklin flew the most famous kite in history. Sparks jumped from a key tied to the bottom of the kite string to the knuckles of his hand (Fig. 1.2). He had verified his theory, and had probably done so before he knew that D'Alibard had already obtained the same proof.

There is some controversy as to whether Franklin flew his kite in June 1752 or later that summer and whether at the time of his experiment he knew of the earlier French results (Refs. 1.3, 1.4). Curiously, it wasn't until 1788 that Franklin himself first wrote that he had performed the kite experiment; and then only a brief sentence was devoted to the subject (Ref. 1.5). Nevertheless, in October 1753 Franklin described the kite experiment in detail and stated that it had succeeded in Philadelphia – but not that he himself had performed it (Ref. 1.6). The classic account of Franklin's kite flight was written by Joseph Priestly in his *History and Present State of Electricity* published 15 years after the flight (Ref. 1.7). Evidence is available to show that Franklin had read Priestly's manuscript before publication and had approved of it (Ref. 1.3).

Kite flying in thunderstorm weather can be dangerous. A number of people have been killed imitating Benjamin Franklin. In the nineteenth and early twentieth century meteorological observations were made by sending instruments aloft on large box kites. In 1898, 17 U.S. Weather Bureau stations were equipped for daily kite ascensions. The kites used weighed 8 lb, carried 2 lb of instruments, and dragged as much as 20 or 30 lb of piano wire beneath them.

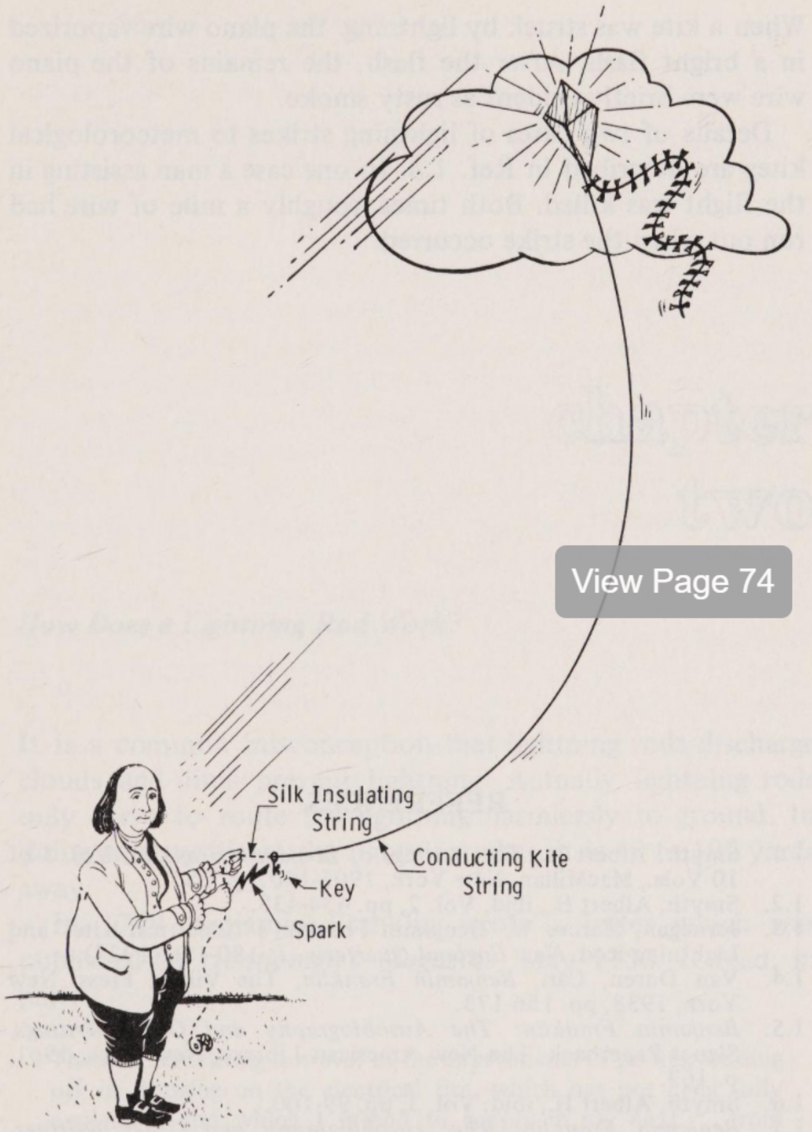

Fig. 1.2. Franklin's electrical kite experiment: Sparks jump from the electrified key at the end of the electrified kite string to Franklin's hand.

When a kite was struck by lightning the piano wire vaporized in a bright flash. After the flash, the remains of the piano wire were briefly evident as rusty smoke.

Details of two cases of lightning strikes to meteorological kites are described in Ref. 1.8. In one case a man assisting in the flight was killed. Both times, roughly a mile of wire had run out when the strike occurred.

chapter two

How Does a Lightning Rod Work?

It is a common misconception that lightning rods discharge clouds and thus prevent lightning. Actually lightning rods only serve to route the lightning harmlessly to ground. In doing so they divert the lightning when it is 10 to 100 yards away.

In 1749 Benjamin Franklin wrote a letter which was published in *Gentlemen's Magazine*, May 1750. It read, in part,

> There is something however in the experiments of points, sending off or drawing on the electrical fire, which has not been fully explained, and which I intend to supply in my next . . . from what I have observed on experiments, I am of opinion that houses, ships, and even towers and churches may be eventually secured from the strokes of lightning by their means; for if instead of the round balls of wood or metal which are commonly

> placed on the tops of weathercocks, vanes, or spindles of churches, spires, or masts, there should be a rod of iron eight or ten feet in length, sharpened gradually to a point like a needle, and gilt to prevent rusting, or divided into a number of points, which would be better, the electrical fire would, I think, be drawn out of a cloud silently, before it could come near enough to strike.

This is Franklin's earliest recorded suggestion of the lightning rod. In the "experiments of points" he placed electrical charge on isolated conductors and then showed that the charge could be drained away (discharged) slowly and silently if a pointed and grounded (attached to ground) conductor were introduced into the vicinity. When the pointed conductor was brought too close to the charged conductor, the discharge occurred violently via an electric spark.

In the discussion in which he proposed the original experiment to determine if lightning were electrical (July 1750 – see Chapter 1), Franklin repeated his suggestion for protective lightning rods, adding that they should be grounded (i.e., that a wire should connect the lightning rod to the ground or, in the case of a ship, to the water).

Lightning rods were apparently first used for protective purposes in 1752 in France and later the same year in the United States (Refs. 2.1, 2.2).

Franklin originally thought – erroneously – that the lightning rod silently discharged the electric charge in a thundercloud and thereby prevented lightning. However, in 1755 he stated:

> I have mentioned in several of my letters, and except once, always in the *alternative, viz.,* that pointed rods erected on buildings, and communicating with the moist earth, would *either* prevent a stroke, or, if not prevented, would *conduct* it, so that the building should suffer no damage. (Ref. 2.3)

It is in the latter manner that lightning rods actually work. The charge flowing between a lightning rod and a thundercloud is much too small to discharge the thundercloud (Ref. 2.4). The rod diverts to itself a stroke on its way to earth but can do so only in the final part of the stroke's earthward trajectory. Diversion is achieved by the initiation of an electrical discharge (Fig. 2.1), a sort of traveling spark, which propagates from the rod, intercepts the downward-moving lightning, and provides a conducting path to the rod. Before the traveling spark is initiated, the downward-moving lightning is essentially uninfluenced by objects on the ground beneath it. The traveling spark is generally 10 to 100 yards long when it meets the lightning.

Any high object may initiate an upward-moving spark which attempts to reach the downward-moving lightning. It is therefore important that the lightning rod be the tallest object near the structure it protects, so that its traveling spark catches the lightning rather than a spark initiated by the chimney or a nearby tree.

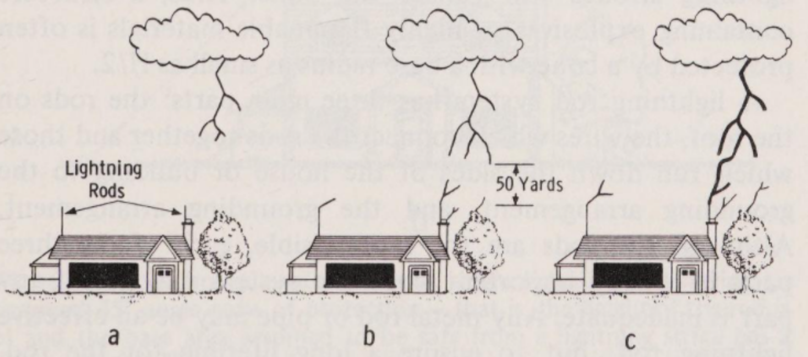

Fig. 2.1. Final stages of a strike to a lightning rod. The time interval between B and A and between C and B is about 1/5000 second. The lightning channel becomes very bright (view C) immediately after the upward-traveling spark connects with the downward-moving lightning. Drawings are not to scale.

Franklin refused to patent the lightning rod or otherwise to profit by its invention.

No lightning rod, however tall, can offer absolute protection; lightning has struck the Empire State Building 50 ft below the top (see Chapter 6). Nevertheless, lightning rod systems are effective if used properly, and many codes have been written to describe their use (Ref. 2.5). A single vertical rod will almost always protect objects within an imaginary cone (the "cone of protection") formed by all lines connecting the top of the rod at height H with a circle on the ground, beneath the rod, of radius between H and 2H. In Fig. 2.2a, the house has a single lightning rod with a cone of protection assumed to have a base radius H in accord with the British lightning code. To protect a large house it is more practical to use multiple lightning rods: in Fig. 2.2b, three cones of protection overlap to provide a large volume of protection without excessive height. The house in Fig. 2.1 is protected according to the U.S. lightning code which specifies a base radius of 2H for the cone of protection. The smaller the base radius, the greater the probability that no lightning strokes will violate the cone. Thus, a structure containing explosives or highly flammable materials is often protected by a cone with a base radius as small as H/2.

A lightning rod system has three main parts: the rods on the roof, the wires which connect the rods together and those which run down the sides of the house or building to the grounding arrangement, and the grounding arrangement. Although the rods are the most visible, each of the three parts is equally important since the system may fail if any part is inadequate. Any metal rod or pipe may be an effective lightning rod, but to ensure a long lifetime for the rod, corrosion-resistant metal such as copper, aluminum, or galvanized iron should be used. There is no evidence that a pointed rod is better than one with a ball on the top. A wide variety of lightning rod shapes can be seen on urban and rural structures.

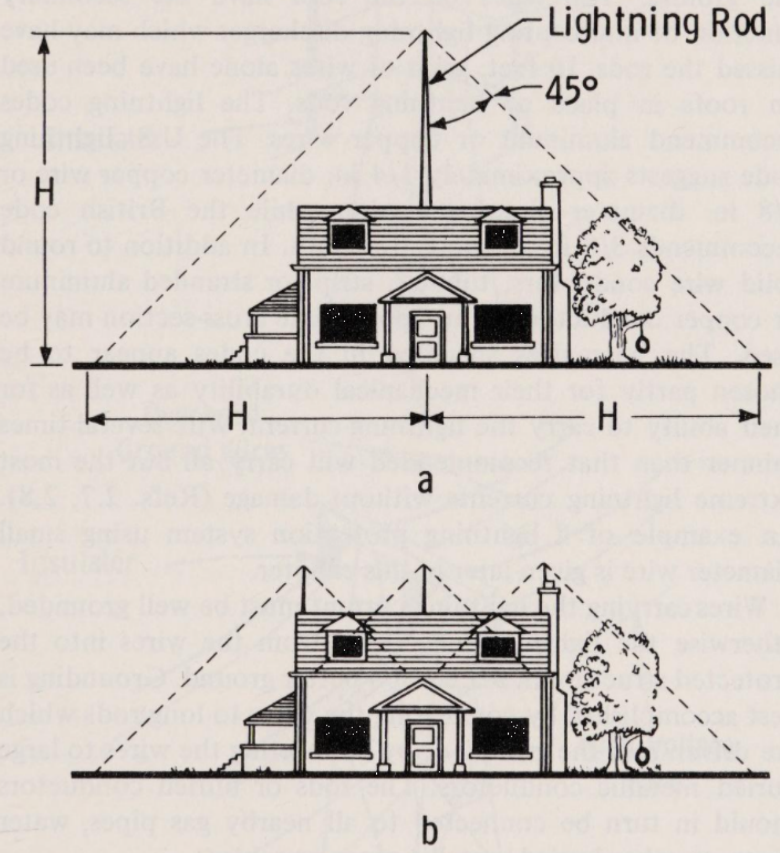

Fig. 2.2. (a) A house protected by a single lightning rod having an assumed 45°-angle cone of protection – that is, the height of the rod is H and the base area assumed to be safe from a lightning strike has a radius H. (b) The same house protected by a lightning rod system consisting of three smaller rods, each assumed to provide a 45°-angle cone of protection.

The primary function of the wires which link the lightning rods and those connecting the rods to the grounding arrangement is to carry the lightning current from the rods to the ground. The wires on the roof have the secondary function of intercepting lightning discharges which may have missed the rods. In fact, grids of wires alone have been used on roofs in place of lightning rods. The lightning codes recommend aluminum or copper wires. The U.S. lightning code suggests approximately 1/4 in. diameter copper wire or 3/8 in. diameter aluminum wire, while the British code recommends 3/8 in. diameter for both. In addition to round solid wire conductors, tubular, strip, or stranded aluminum or copper conductors of an appropriate cross-section may be used. The wire sizes specified in the codes appear to be chosen partly for their mechanical durability as well as for their ability to carry the lightning current. Wire several times thinner than that recommended will carry all but the most extreme lightning currents without damage (Refs. 2.7, 2.8). An example of a lightning protection system using small diameter wire is given later in this chapter.

Wires carrying the lightning current must be well grounded, otherwise the lightning may jump from the wires into the protected structure in search of a better ground. Grounding is best accomplished by connecting the wires to long rods which are driven into the ground or by connecting the wires to large buried metallic conductors. The rods or buried conductors should in turn be connected to all nearby gas pipes, water pipes, or other buried metallic pipes or cables.

It is sometimes imperative to keep the lightning current and possible attendant sparks from contacting any part of a protected structure – a typical case being a liquid-fuel storage vat in which flammable vapors are present. Here, the roof rods and wire conductors are often replaced by a system of wires suspended between tall towers arranged around the structure. A similar scheme is used to protect high voltage

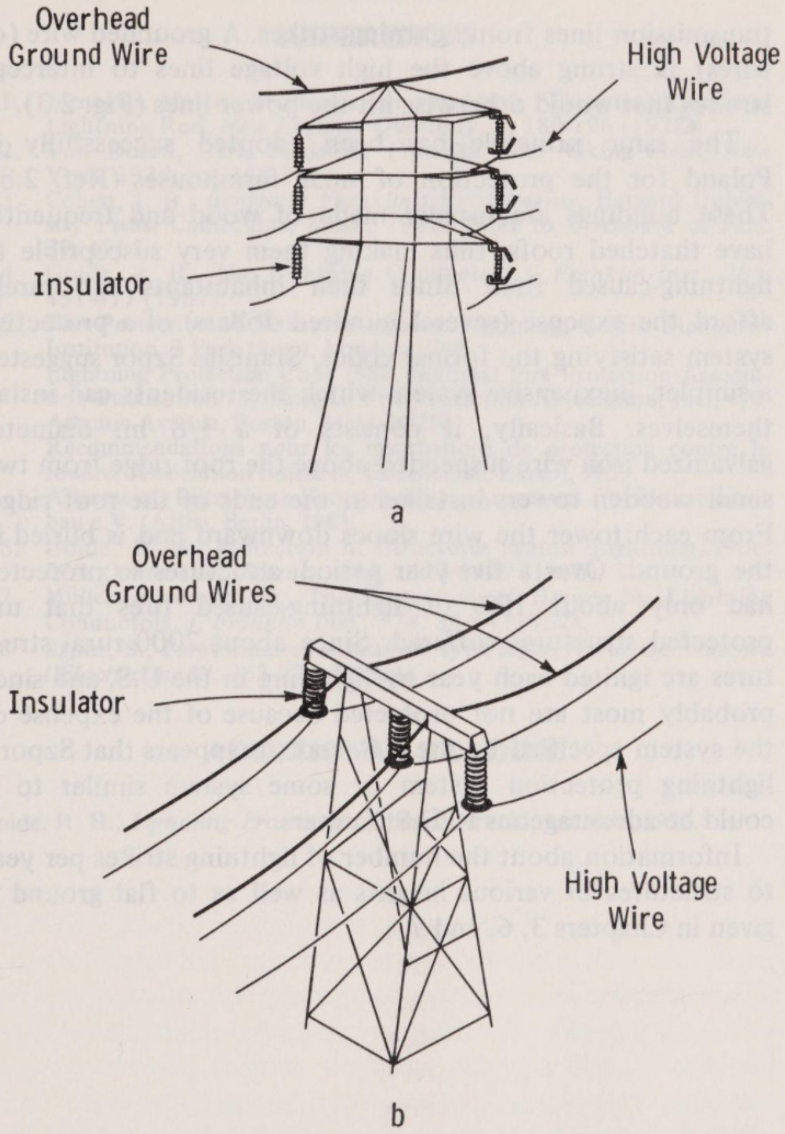

Fig. 2.3. Use of overhead ground wires to protect high voltage transmission lines from lightning. Each of the high voltage wires is supported by the bottom of an insulator. Ground wires are attached to the metal transmission line towers which are well grounded. Drawings are not to scale. (a) A typical 132,000 volt line. (b) A typical 220,000 volt line.

transmission lines from lightning strikes. A grounded wire (or wires) is strung above the high voltage lines to intercept strokes that would otherwise hit the power lines (Fig. 2.3).

The same principle has been adopted successfully in Poland for the protection of small farmhouses (Ref. 2.8). These buildings are usually made of wood and frequently have thatched roofs, thus making them very susceptible to lightning-caused fires. Since their inhabitants can rarely afford the expense (several hundred dollars) of a protective system satisfying the formal codes, Stanislas Szpor suggested a simpler, inexpensive system which the residents can install themselves. Basically, it consists of a 1/8 in. diameter galvanized iron wire suspended above the roof ridge from two small wooden towers installed at the ends of the roof ridge. From each tower the wire slopes downward and is buried in the ground. Over a five-year period, structures so protected had only about 10% of lightning-caused fires that unprotected structures suffered. Since about 2000 rural structures are ignited each year by lightning in the U.S. and since probably most are not protected because of the expense of the system specified by the U.S. code, it appears that Szpor's lightning protection system or some system similar to it could be advantageous to U.S. farmers.

Information about the number of lightning strikes per year to structures of various heights as well as to flat ground is given in Chapters 3, 6, and 7.

chapter three

How Many People Are Killed By Lightning Each Year?

What Should I Do If Caught Outdoors In A Thunderstorm?

Is It Safe To Talk On The Telephone During A Thunderstorm?

Should I Unplug Radios And TVs?

How Can I Help Someone Struck By Lightning?

Although no exact figures on lightning fatalities are available – there is no central agency to which lightning accidents must be reported – various studies (Refs. 3.1, 3.2, 3.3, 3.4) have placed the average annual number of deaths in the U.S. at 100, 137, 151, 300, and even 600. Whatever the exact number, lightning causes more direct deaths than any other weather phenomena. Snowstorms cause more indirect deaths (e.g., heart attacks from shoveling the driveway). Tornadoes cause about half as many deaths as lightning but inflict much more property damage. It is perhaps surprising that about two-thirds of the people involved in lightning accidents subsequently make a complete recovery. Most, if not all, of these survivors are probably not directly struck by lightning, but rather receive electrical shock from being in the close vicinity of a strike.

About 70% of all fatal lightning accidents involve one person, about 15% occur in groups of two, the remainder involves three or more deaths per lightning event. Between 75 and 85% of all lightning deaths and injuries are to men, probably because they are more likely to be out-of-doors. About 70% of all injuries and fatalities occur in the afternoon, about 20% between 6 p.m. and midnight (Ref. 3.1).

The largest single category of lightning deaths (12 to 15% of all fatalities) is composed of those unfortunate individuals who seek refuge under trees during thunderstorms and have their sheltering trees struck by lightning. Perhaps one-third of these are golfers. Two additional categories in which large numbers of lightning fatalities occur are designated "Open Water" and "Tractors", each claiming about 10% of the total fatalities. "Open Water" includes people fishing, swimming, on beaches, piers, and levees, in boats, and on water skis; "Tractors" includes people on, in, or near farm tractors or other implements, construction equipment, cars, and trucks (Refs. 3.1, 3.3).

Most lightning deaths occur outdoors. Over 30% of all lightning deaths involve people who work outdoors; over 25% of all deaths involve outdoor recreationists. A breakdown of deaths and injuries to farmers and ranchers and to outdoor recreationists for the 20-year period 1950 through 1969 is given in Table 3.1. The apparent increase from the 1950s to the 1960s in the number and percentage of deaths to outdoor recreationists is perhaps due to the increasing number of outdoor recreationists. Table 3.2 gives more detailed data on death and injury to outdoor recreationists, while Table 3.3 breaks down the "Open Water" category of Table 3.2.

In addition to humans, animals are killed by lightning. In 1968, lightning caused the death of 464 cattle (362 killed directly, the remainder by lightning-caused fires), 13 horses (11 killed directly), 42 hogs, 2 dogs, and 1 white ox resident in a museum pasture (Ref. 3.4).

flow in the metal skin of the car and not in the occupant. The lightning will ground itself by jumping from the car to the earth either through the air, along the surface of a tire, or through a tire. In the latter case, the tire will be destroyed. For maximum security, the car windows should be rolled up and wet (so that they conduct current along their surfaces), and the occupant should not touch any metal part of the car or the car radio.

Because modern commercial aircraft are essentially all metal, lightning currents seldom penetrate them. An airplane *on the ground* is a relatively safe refuge during a thunderstorm. What about planes in the air? Are aircraft in flight hit by lightning? If hit, do they continue to fly?

Airplanes in flight *are* struck by lightning. Between January 1965 and December 1966, the Federal Aviation Administration (FAA) collected reports of about 1000 lightning strikes to commercial aircraft. On the average, a given commercial airplane is struck by lightning once in every 5000 to 10,000 hours of flying time (Refs. 4.1, 4.2). As extreme examples of lightning activity, on one day in January 1969 four airliners were hit by lightning in separate incidents near Los Angeles (Ref. 4.3), and on September 26, 1964 a Boeing 727 in a holding pattern at Chicago was hit by lightning five separate times within a 20-minute period (Ref. 4.4).

Aircraft struck by lightning almost always continue to fly. Generally, lightning leaves pit marks or burn marks on the aircraft's metallic skin or burn or puncture holes through it. The FAA reports hole diameters up to 4 in., a common size being 1/2 in. (Ref. 4.1). Photographs of a lightning-damaged aircraft wing are shown in Figs. 4.1, 4.2, and 4.3. In addition to the generally minor damage caused to metallic aircraft parts, unprotected non-metallic parts may be more severely damaged. (Differences between lightning damage to metallic and non-metallic materials are discussed in the next chapter.)

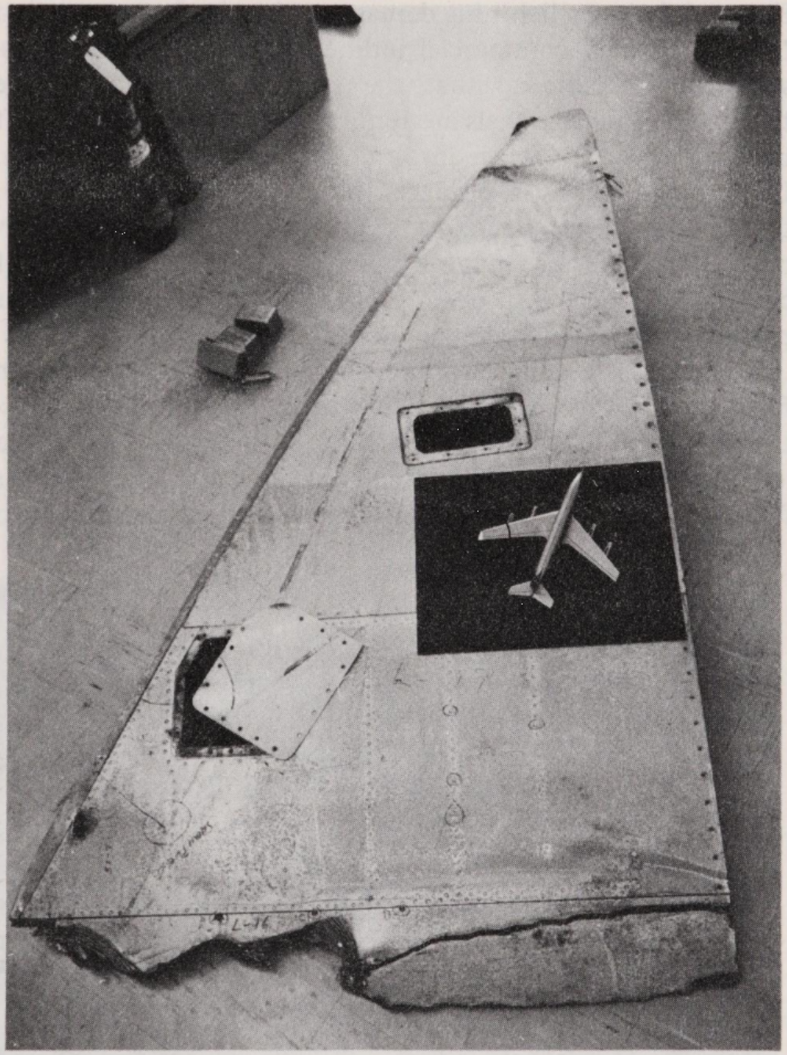

Fig. 4.1. Left wing tip of a Boeing 707 which exploded after being hit by lightning near Elkton, Maryland on December 8, 1963. On the model insert the white portion of the wing gives the size and orientation of the portion of the actual wing shown. A number of lightning-caused holes and considerable pitting are evident. (Courtesy, Bernard Vonnegut and Roger Cheng, State University of New York at Albany)

Figure 4.4 shows lightning damage to the plastic nose section or radome of a commercial jetliner. (The radome is necessarily non-metallic so that the plane's radar can operate through it – radar signals are reflected by metal.) The aircraft in Fig. 4.4 had its radar unit put out of commission. Lightning is clearly a potential hazard. On the other hand, thunderstorm turbulence is a greater hazard. Severe turbulence can cause structural failure of the aircraft or loss of control by the pilot. The problem of loss of control is particularly critical during take-off and landing.

Lightning is a danger to aircraft for several reasons. It can fuse, burn away, or otherwise destroy mechanical or electrical parts; it can temporarily blind the pilot causing him to lose control of the aircraft; and it can ignite the aircraft's fuel. Fuel ignition was the probable cause of the only two

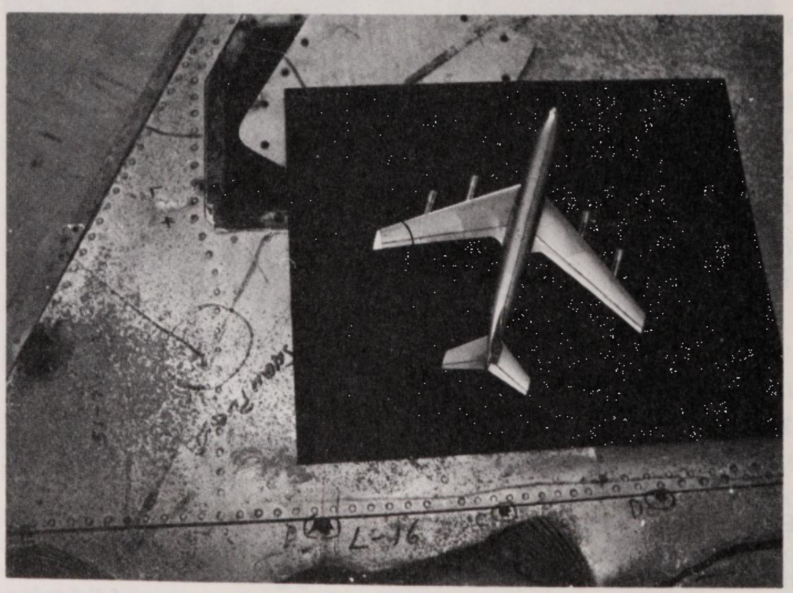

Fig. 4.2. Closer view of the Boeing 707 wing tip shown in Figure 4.1. Five lightning-caused holes are visible. (Courtesy, Bernard Vonnegut and Roger Cheng)

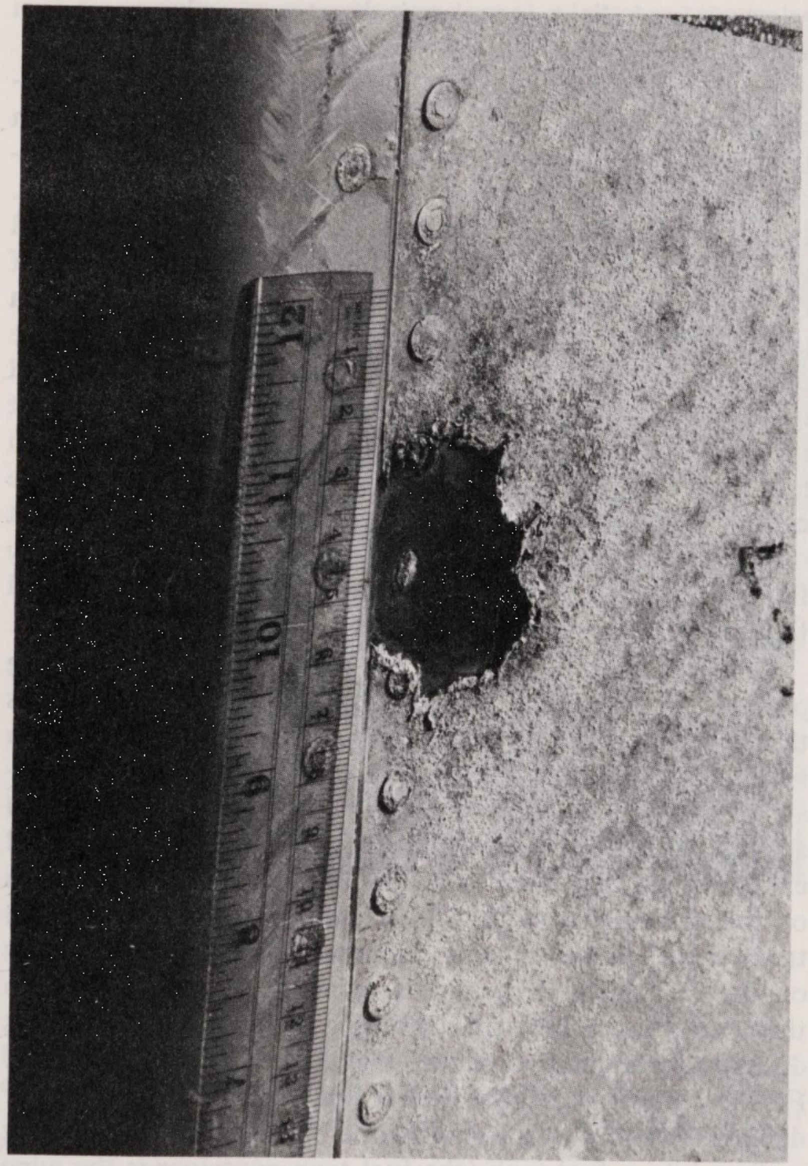

Fig. 4.3. Close-up of the major wing-tip hole and surrounding pitting shown at the left of Figures 4.1' and 4.2. (Courtesy, Bernard Vonnegut and Roger Cheng)

acknowledged lightning-related disasters involving modern commercial aircraft.

On June 26, 1959 near Milan, Italy, a Lockheed Constellation, a propeller-driven U.S. air carrier, was climbing in thunderstorm activity through about 11,000 ft when structural disintegration occurred. All persons aboard were killed. Investigation revealed that two of the fuel tanks had exploded. Fuel vent pipes extending off the trailing edges of the wings were exhausting air and fuel vapors (to maintain a pressure inside the fuel tank equal to the decreasing pressure outside, as the plane climbed) and were a likely point for fuel ignition. It is not clear whether lightning struck a fuel vent pipe or whether a traveling spark (similar to those which leave lightning rods; Chapter 2) was initiated at the pipe causing ignition. In either event, it is probable that some sort of electric spark ignited the fuel at the vent pipe, the burning fuel propagated into the number 6 and 7 fuel tanks, and those fuel tanks exploded (Ref. 4.1).

On December 8, 1963, a Boeing 707 was in a holding pattern at 5000 ft near Elkton, Maryland. There was thunderstorm activity in the area. Witnesses reported a lightning stroke near the aircraft concurrent with or immediately followed by explosion and burning of the 707. All aboard were killed. It was found that three fuel tanks had exploded and that there were lightning strike marks and holes on the left wing tip (Figs. 4.1, 4.2, 4.3). Exactly how the fuel tanks were ignited remains unknown. The fuel vent outlets on the 707 are underneath the wings and are recessed into them, so it is unlikely that lightning could strike the outlets directly or that they could be the source of traveling sparks. Further, when recovered, the vent outlets showed no signs of damage. Possibly a lightning stroke burned through the wing surface into a fuel tank (the fuel tank container is the wing skin). No evidence for this effect was found, although the explosion might have destroyed any pertinent evidence. The

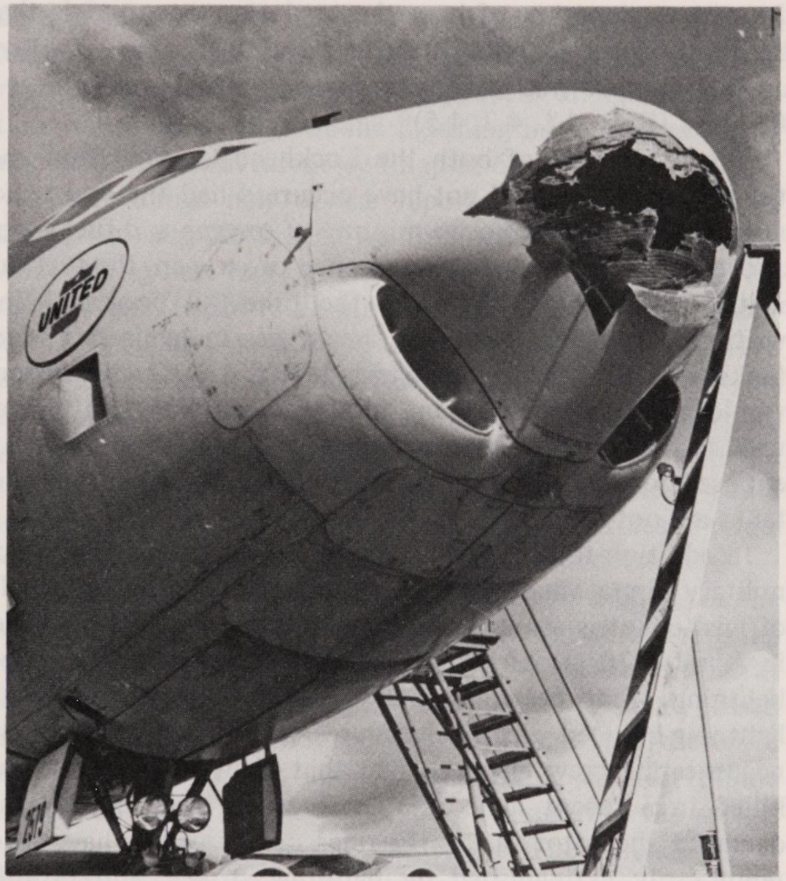

Fig. 4.4. Lightning damage to the radome of a commercial jetliner — one of four planes hit by lightning on one day in January 1969 in separate incidents near Los Angeles (Ref. 4.3). ("Los Angeles Times" photograph)

favored explanation of how the explosion occurred is that lightning caused sparks at some point where an explosive air-fuel mixture was present, perhaps in a fuel tank or near a fuel leak (Refs. 4.1, 4.2, 4.5).

The explosions of both the Lockheed Constellation and the Boeing 707 would not have occurred had the fuel tanks not contained an explosive mixture of oxygen and fuel vapor above the liquid fuel. In the absence of oxygen, the fuel can neither burn nor explode. At the time this book is being written, systems for replacing the oxygen in an aircraft's fuel tanks with nitrogen are being tested (Ref. 4.2). Such a system would make aircraft immune to explosions from lightning as well as from fires due to accidents in which the fuel is not exposed to the oxygen of the air (accidents in which the fuel tanks are not ruptured).

In addition to these two commercial aircraft, a number of military aircraft have also been destroyed by lightning. No official count is available, but it is known that, for example, in April 1970 an Air Force jet exploded after being hit by lightning, that there have been several recent cases of lightning-induced electrical failures on jet aircraft in flight necessitating crew ejection, and that eight servicemen were killed in a recent helicopter crash when lightning hit and damaged the rotor blades. Engines on many jets have been temporarily extinguished by lightning strikes, and in July 1969 a lightning strike to a jet resulted in two bombs being released.

When lightning strikes a plane, the plane substitutes for part of the lightning's air path. Typically lightning attaches to the plane's extremities, often entering at one wing tip and leaving by the top of the tail. When a lightning stroke is forming near a plane, the extremities of the plane send out traveling sparks to meet that lightning and cause it to pass through the plane, much as a lightning rod draws the lightning to itself. Thus a plane may attract lightning. In

addition, a plane may fly into an already existing lightning channel and become a part of the channel, or it may initiate a brand new lightning stroke. The process of lightning initiation is similar to that of the lightning initiation caused by tall conducting structures (see Chapter 6).

In only about half of the reported lightning strikes to commercial aircraft are active thunderstorms present (Ref. 4.4). The other half of the reported strikes occurs in precipitation (ice or rain) which is not related to a thunderstorm. Typically, in these cases no lightning is observed before the strike which hits the plane. There appears to be no difference between thunderstorm and non-thunderstorm lightning as regards damaging effects to an aircraft. Undoubtedly, thunderstorm-related lightning strikes would represent a much higher percentage of total strikes if pilots did not intentionally avoid flying through thunderstorms.

It is interesting to note that Apollo 12 (launched for the moon on November 14, 1969) was twice struck by lightning in the first minute after lift-off, once at 6000 ft and again at 13,000 ft. The clouds through which the 360 ft rocket passed had not previously produced any lightning. It is therefore likely that the rocket and its conducting exhaust plume initiated the two discharges. Apollo 12 survived the strikes although their effects were considerable. They included: (1) temporary disconnection of the fuel cells which powered the command module systems, (2) temporary disruption of the primary inertial guidance system used to put the spacecraft into and out of earth orbit and on its way toward the moon, and (3) permanent loss of a number of measurements of the skin temperature of the rocket and of the quantity of propulsion fuel remaining (Ref. 4.6).

From 1964 to 1966 a F-100F jet fighter aircraft, specially protected against the hazardous effects of lightning and equipped to photograph lightning and to measure its electrical current, pressure wave (see Chapter 12), and other properties, was deliberately flown through thunderstorms (Refs. 4.2, 4.7). The plane was struck by lightning 55 times and much valuable information was accumulated.

Ball lightning inside airplanes is discussed in Chapter 15.

chapter five

How Does Lightning Damage Trees And Buildings?

As discussed in Chapter 7, roughly 2000 thunderstorms are in progress over the earth's surface at a given time, and collectively they may produce as many as 100 cloud-to-ground discharges each second – or more than 8 million per day. If these discharges were evenly distributed over the earth, about six percent of them would strike in the world's forested lands (Ref. 5.1). Fortunately, most discharges striking in forests do not cause forest fires. Nevertheless, about 10,000 forest fires are ignited by lightning in the United States each year.

Lightning may strike a tree and leave it apparently unharmed (Ref. 5.2), or it may cause considerable structural damage without noticeable burning. The detailed effects of lightning on trees have been recently studied by Alan R. Taylor of the U.S. Forest Service (Refs. 5.1, 5.3, 5.4, 5.5, 5.6). He found that most trees struck are not killed. The majority recover from whatever lightning damage they have sustained, though many are weakened and ultimately succumb to attacks by insects and disease. Visible damage to tree trunks ranges from superficial bark flaking, to strip-like furrowing along the trunk, to almost total destruction. Damage of intermediate severity is shown in Fig. 5.1: the tree top has been shattered away and a spiral scar with a crack along its axis is wound around the trunk. A close-up of how typical lightning tree scars are formed is shown in Fig. 5.2. Figures 5.3 and 5.4 show lightning-damaged trees.

Taylor, in one study, examined 1000 lightning-damaged Douglas firs in western Montana. Most had shallow continuous scars a few inches wide along their trunks. About 20% had two or more scars, 10% had severed tops, and about 1% had been reduced to slabs and slivers. Most of the scars were spiral, a few were straight. The average scar extended along 80% of the tree height, but none extended to the very tips of the trees. Scars either reached to ground level or close to ground level. Often along the center line of the lightning scar was a crack which penetrated into the tree (Figs. 5.1 and 5.2), and, when wood was removed from a tree by lightning, it was usually ejected as two parallel slabs, separated along this crack. Sometimes, in place of the crack lightning left a narrow strip of shredded inner-bark fiber fixed in a smooth shallow groove about 1/16-in. wide (Fig. 5.5).

These damage characteristics are typical not only for Douglas firs but for most conifers (cone bearing trees, mostly evergreens) throughout the United States. The descriptions also appear valid for most rough-barked species of deciduous trees (trees which shed their leaves each year) such as the oaks. The relatively smooth barks of other deciduous trees – birches, for example – present quite different damage characteristics. The major difference is that the bark is not removed in narrow, uniform strips but is torn off in large, somewhat irregular patches or sheets (Fig. 5.6).

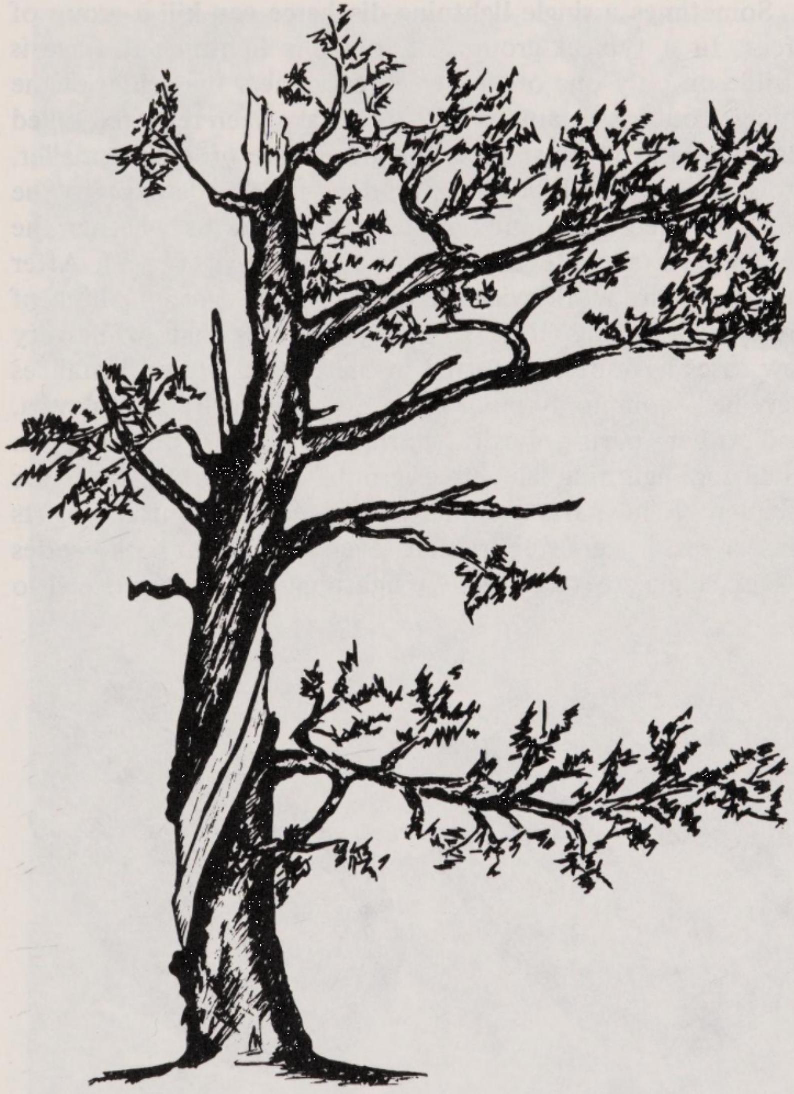

Fig. 5.1. The top of this Douglas fir was shattered away and a spiral lightning scar with a crack along its axis winds around the trunk. (Field sketch by A. R. Taylor)

Sometimes a single lightning discharge can kill a group of trees. In a typical group kill, obvious lightning damage is visible on only one or two trees, often near the center of the dying group. As many as 160 trees have been reported killed this way, but in most cases the groups are probably smaller. It is unclear whether lightning does unseen damage to the roots of trees surrounding the struck tree or whether the aerial parts are affected by the discharge (Ref. 5.7). After reviewing the world-wide literature on the group killing of trees by lightning (Ref. 5.1), Taylor notes that, while very few cases have been reported in the United States, instances have been commonly reported in Europe, Australia, Malaysia, and other parts of the world. A similar phenomenon involving lightning and tree groups is reported to occur frequently in parts of the United States. Entomologists (insect researchers) report that several species of bark beetles attack single trees damaged by lightning and then proceed to

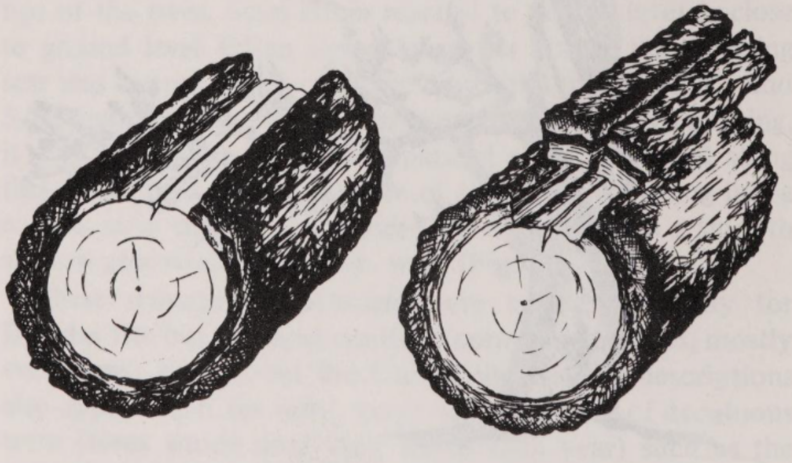

Fig. 5.2. Formation of typical lightning tree scars. Left, bark and wood loss; right, bark loss only. Bark and wood removed in this way are usually found in two slabs. The slabs have been separated along the crack at the centerline of the tree scar. (Sketch by A. R. Taylor)

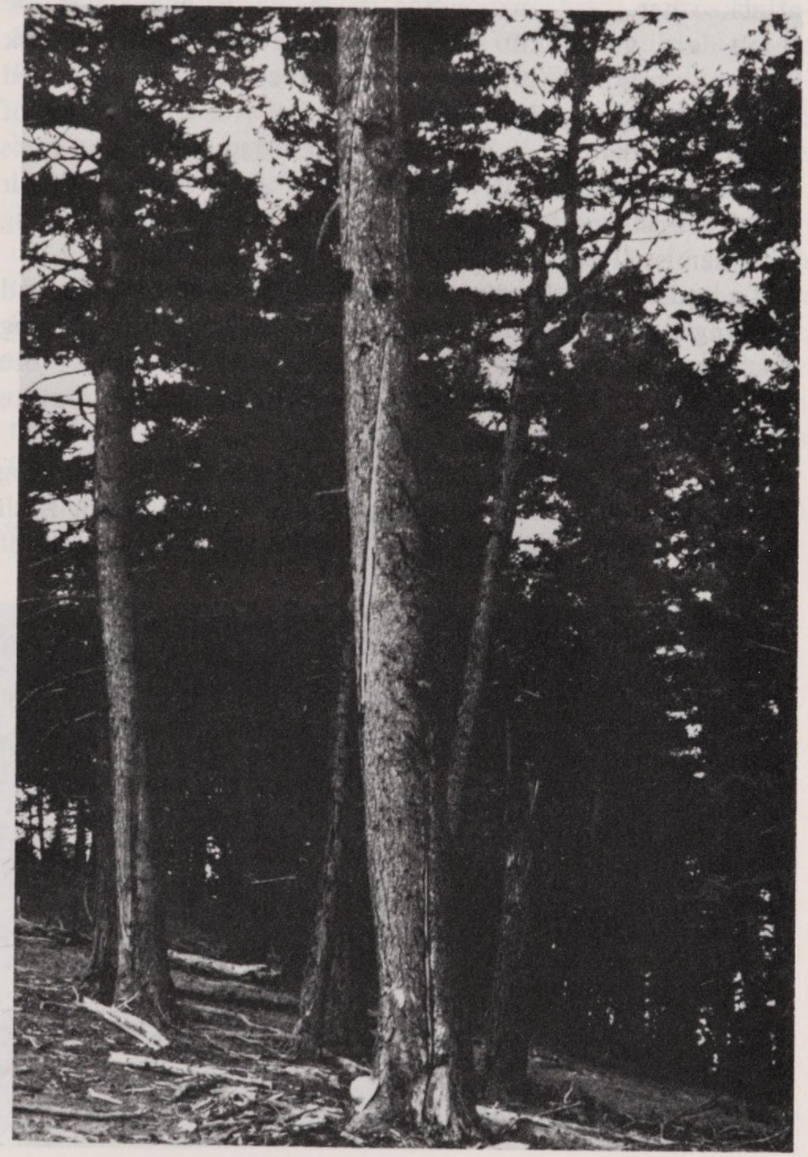

Fig. 5.3. A Douglas fir with three spiral lightning scars. Only bark was removed, exposing the outer wood. (U.S. Forest Service photo)

attack other trees surrounding the damaged one. Often the result is a group kill similar to those not involving bark beetles – so similar in fact that it has recently been suggested that lightning may be playing a hidden role in this type of group kill; that is, it may do unseen damage to the trees surrounding an obviously struck tree, thereby reducing their natural resistance to attack by the bark beetles and hastening their demise (Refs. 5.6, 5.8).

To understand the direct effects of lightning on trees and buildings, we must first take a closer look at the lightning discharge. In the course of this discussion we will define more specifically some of the words used in the technical literature to describe lightning.

A complete lightning discharge is called a *flash.* A lightning flash typically lasts a few tenths of a second. Each flash between cloud and ground is composed of a number of component strokes. The number is sometimes one (a single-stroke flash), most often is three or four (multiple-stroke flash), and may be as many as 20 or 30. Strokes are typically 40 or 50 thousandths of a second apart. Cloud-to-ground lightning often appears to flicker due to the fact that the lightning channel is dark between the component strokes. The longer the time between strokes, the greater the flickering effect. When strokes are very close together (e.g., when they are separated by only 20 thousandths of a second), little flickering is observed because the eye retains the image of the stroke during the "dark time". It is this slow response of the eye that makes movies and TV appear continuous rather than the series of individual pictures that comprise them. Movies that are run too slowly also appear to flicker.

The bright stroke channels we see (an example is shown in Fig. 2.1c) and the stroke currents which cause the light are

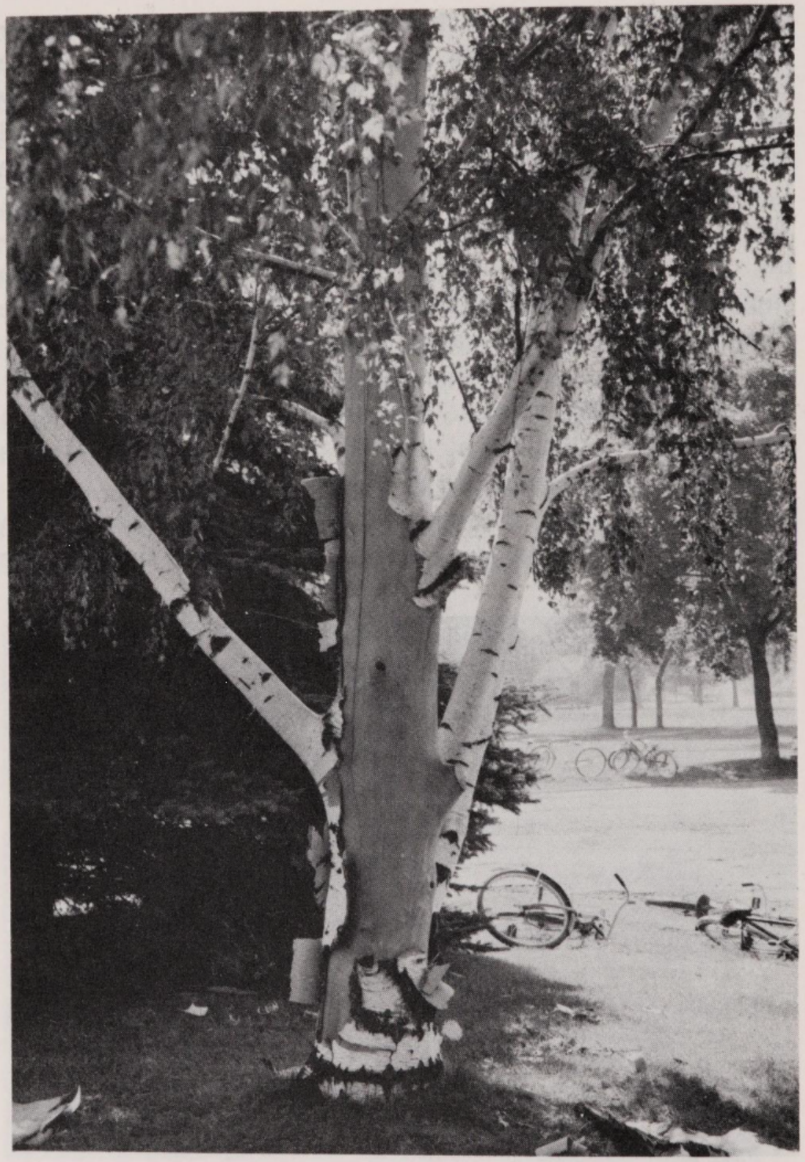

Fig. 5.6. Lightning removed bark from this paper birch in large, irregular patches. (U.S. Forest Service photo)

initiated by electrical discharges which move from cloud to ground (a discharge preceding the first stroke of a flash is shown in Fig. 2.1a,b). (Details of the lightning stroke formation are given in Chapters 6 and 9.)

Typical lightning currents measured at ground are shown in Fig. 5.7 (Ref. 5.9). Peak currents are generally 10,000 to 20,000 amps, but occasionally they range up to hundreds of thousands of amps. (The conventional household electric circuit will carry up to 15 amps. A 100 watt light bulb uses about 1 amp.) First strokes generally have larger currents than subsequent strokes. A lightning stroke reaches peak current in a few millionths of a second. The current then decreases, generally terminating in a thousandth of a second or so unless continuing current flows. Figure 5.7a shows a three-stroke flash with no continuing current. Figure 5.7b

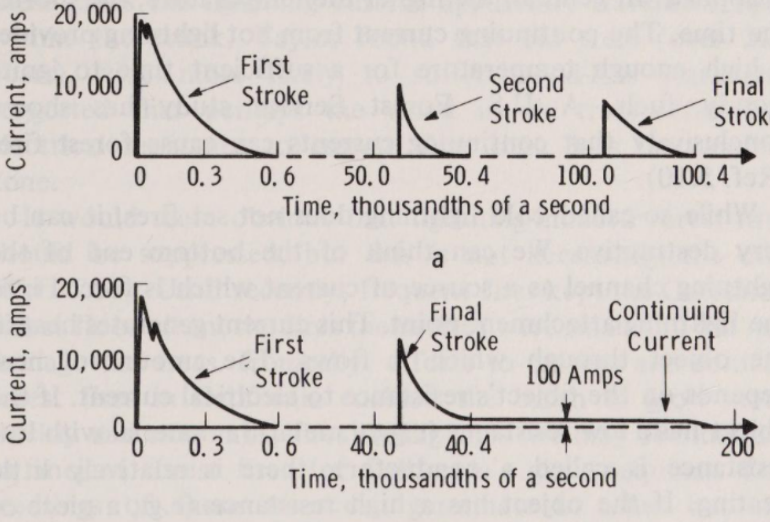

Fig. 5.7. (a) Current at ground due to a typical lightning flash without continuing current – so-called cold lightning. (b) Current at ground due to a typical lightning flash with continuing current – so-called hot lightning.

shows a two-stroke flash in which the final stroke is followed by continuing current. Continuing current is typically 100 amps and may last for one or two tenths of a second. About half of all flashes contain a continuing current following one of the component strokes.

Lightning flashes which contain continuing current are commonly called *hot lightning;* flashes which do not are called *cold lightning.* Hot lightning sets fires, cold lightning does not. The reason for the terminology is obvious. It is, nevertheless, misleading. The temperature in both hot and cold lightning is the same – 15,000 to 60,000°F (see Chapter 11). The difference is that it is maintained longer in hot lightning (tenths of a second vs. thousandths for cold lightning). To set fire to a piece of wood, the flame must contact the wood for a reasonable length of time: initiation of burning depends on the length of time a given temperature is applied. In general, the higher the temperature, the shorter the time. The continuing current from hot lightning provides a high enough temperature for a sufficient time to ignite woody fuels. A U.S. Forest Service study has shown conclusively that continuing currents can cause forest fires (Ref. 5.10).

While so-called cold lightning does not set fires, it can be very destructive. We can think of the bottom end of the lightning channel as a source of current which is forced into the lightning attachment point. This current generates heat in the object through which it flows. The amount of heat depends on the object's resistance to electrical current. If the object has a low resistance (e.g., a metal) (a material with low resistance is called a conductor), there is relatively little heating. If the object has a high resistance (e.g., a piece of wood or plastic), there is a great deal of heating although not necessarily enough to cause burning. The essentially instantaneous lightning current rise inside a high-resistance material causes rapid heating and consequent vaporization (i.e., conversion from solid to gas) of some of the internal material. As a result, a very high pressure is quickly generated within the material and, typically, this pressure blows the material apart.

For many of the tree scars examined by Taylor, the lightning apparently followed a path through the cambium (a thin layer of living cells between the inner bark and the wood) or through the moist inner bark tissue. Possibly these zones were chosen as the lightning's paths because they offered lower resistance than the outer bark or the wood. In any event, the pressure generated in the cambial region blew off a bark strip creating a scar as shown in Fig. 5.5. The pressure also could cause a split in the tree, but it is not clear how a strip of inner-bark fiber could be pasted along the centerline of the scar. In some of the trees examined by Taylor, wood as well as bark was blown out from the tree. In these cases the lightning current apparently traveled deeper within the trunk. Taylor found that old trees (over 200 years) were more likely to suffer wood-loss scars and suggested that perhaps the wood in old trees offers less electrical resistance to current flow than does the cambial zone.

It would seem obvious that lightning-induced forest fires should be suppressed, but this is not necessarily the case (Ref. 5.11). Until recently, frequent fires kept the California forest floor clean; the fires themselves were small and did not damage the trees. Ironically, efforts to prevent and contain forest fires in California enabled the brush to grow more thickly and now most fires are big ones. We may be indebted to ancient forest fires for California's giant sequoias. The seedlings of these trees can germinate in ashes but are suppressed under the thick layer of needles that might cover an unburned forest floor.

From all the foregoing discussion it is obvious that houses can be set on fire by lightning and that high-resistance material comprising houses can be blown apart. Besides directly setting fire to houses and other structures, lightning can indirectly set fires by causing the power company's current to jump through the air between electrical wires or from a wire to a grounded object. The resulting electrical discharge may have a considerably longer duration than the lightning flash which started it. The only known way to protect a house against a direct lightning strike is with a lightning rod system (see Chapter 2). Similarly, the only known way to protect a tree against lightning is to outfit it with a similar rod system. This would consist of metal wire or strip fixed to the tree from a well-established ground and running up the tree trunk to the top of the tree and out the major branches. Thus lightning striking the tree top or any major branch would be harmlessly carried to earth.

chapter six

Does Lightning "Never Strike Twice?"

Does It Always Strike The Tallest Object?

Much of what is known about lightning today has been discovered precisely because lightning *does* strike the same structure over and over again. To measure a given property of many lightning strokes (for example, the range of values for the peak current), it is necessary to position appropriate instrumentation close to many lightning strokes. The Empire State Building in New York City is struck by lightning an average of about 23 times per year. As many as 48 strikes have been recorded in one year, and during one thunderstorm eight strikes occurred within 24 minutes (Refs. 6.1, 6.2). The General Electric Company conducted a 10-year study (1935-1941, 1947-1949) of lightning at the Empire State Building. Various properties of the lightning current were measured as the current flowed into the building, and high-speed photographs of the formation of the lightning channel near the top of the building were obtained. A similar but more detailed study of lightning was begun on Mount San Salvatore near Lugano, Switzerland in 1942 and still continues at the time of the writing of this book. The instrumented towers near Lugano have recorded lightning current properties an average of about 40 times a year, with a maximum in excess of 100 times a year (Ref. 6.3). A sizable fraction of what we know about lightning currents and, in fact, about lightning in general was determined by the Empire State Building and Lugano studies.

The probability of a structure being struck by lightning depends on its height. For a structure projecting above a moderately flat area in a region of moderate thunderstorm activity, say Pennsylvania or New York (see Chapter 7), the expected number of strikes per year is roughly one for a 300 ft structure, three for a 600 ft structure, five for an 800 ft structure, ten for a 1000 ft structure, and twenty for a 1200 ft structure (Ref. 6.4). A 50 ft structure will be struck about once every four to six years (Refs. 6.2, 6.4), and a quarter acre of flat land (a large residential lot) will be struck about once every 100 years or more (see Chapter 7). Any structure, no matter what its size, may be struck by lightning. Sometimes, however, it is necessary to rebuild the structure before it can be struck again. The bell tower of St. Mark's in Venice was completely destroyed by lightning three times and severely damaged nine times in a period of about 400 years. In 1766 a lightning rod was installed on the tower and since then no further lightning damage has occurred (Refs. 6.5, 6.6).

It is interesting to note that as late as the 18th century church bells were rung in Europe as an effort to protect against lightning. The "ignorant" believed that the ringing of church bells dispersed the evil spirits; the "informed" believed (erroneously) that the sound produced by the bells broke the continuity of the lightning path. Medieval church bells are often inscribed *Fulgura frango* (I break the

lightning). Ringing church bells during thunderstorms proved very hazardous to the bell-ringers. In a period of 33 years, 386 church towers were struck, and 103 bell-ringers were killed at their ropes (Refs. 6.5, 6.6).

Since lightning preferentially strikes the taller structures, it is reasonable to ask whether tall structures merely act as lightning rods or whether they influence the lightning to a greater extent. The question is important since much of what we know about lightning comes from studies of lightning strikes to tall buildings. Scientists and engineers would like to be certain that lightning characteristics so obtained also apply to lightning which strikes small buildings, power lines, missiles, etc. The Empire State Building study was the first to show that most of the flashes to a very tall structure are initiated by the structure itself. In the Lugano study about 75% of the flashes observed were initiated by the towers. These structure-initiated flashes differ significantly from the usual cloud-to-ground flash. Flashes to very tall structures which are not structure-initiated are thought to resemble the usual lightning to ground, but there is still some dispute about this.

It is appropriate now to look at how lightning gets started. The usual flash between cloud and ground is initiated in the base of the cloud. The initiating discharge, the downward-traveling spark shown in Fig. 2.1a,b, is called the *stepped leader*. The stepped leader is a low-luminosity traveling spark which moves from the cloud to the ground in rapid steps about 50 yards long. Each step takes less than a millionth of a second, and the time between steps is about 50 millionths of a second. The stepped leader is not seen by the eye, but may be photographed with special cameras (see Chapter 16, Fig. 16.3). The visible lightning flash discussed in the previous chapter occurs when the stepped leader contacts the ground. Precisely what happens when the stepped leader reaches the ground is the subject of Chapter 9. What is important to note now is that the usual stepped leader starts from channel near the top of the building were obtained. A similar but more detailed study of lightning was begun on Mount San Salvatore near Lugano, Switzerland in 1942 and still continues at the time of the writing of this book. The instrumented towers near Lugano have recorded lightning current properties an average of about 40 times a year, with a maximum in excess of 100 times a year (Ref. 6.3). A sizable fraction of what we know about lightning currents and, in fact, about lightning in general was determined by the Empire State Building and Lugano studies.

The probability of a structure being struck by lightning depends on its height. For a structure projecting above a moderately flat area in a region of moderate thunderstorm activity, say Pennsylvania or New York (see Chapter 7), the expected number of strikes per year is roughly one for a 300 ft structure, three for a 600 ft structure, five for an 800 ft structure, ten for a 1000 ft structure, and twenty for a 1200 ft structure (Ref. 6.4). A 50 ft structure will be struck about once every four to six years (Refs. 6.2, 6.4), and a quarter acre of flat land (a large residential lot) will be struck about once every 100 years or more (see Chapter 7). Any structure, no matter what its size, may be struck by lightning. Sometimes, however, it is necessary to rebuild the structure before it can be struck again. The bell tower of St. Mark's in Venice was completely destroyed by lightning three times and severely damaged nine times in a period of about 400 years. In 1766 a lightning rod was installed on the tower and since then no further lightning damage has occurred (Refs. 6.5, 6.6).

It is interesting to note that as late as the 18th century church bells were rung in Europe as an effort to protect against lightning. The "ignorant" believed that the ringing of church bells dispersed the evil spirits; the "informed" believed (erroneously) that the sound produced by the bells broke the continuity of the lightning path. Medieval church bells are often inscribed *Fulgura frango* (I break the lightning). Ringing church bells during thunderstorms proved very hazardous to the bell-ringers. In a period of 33 years, 386 church towers were struck, and 103 bell-ringers were killed at their ropes (Refs. 6.5, 6.6).

Since lightning preferentially strikes the taller structures, it is reasonable to ask whether tall structures merely act as lightning rods or whether they influence the lightning to a greater extent. The question is important since much of what we know about lightning comes from studies of lightning strikes to tall buildings. Scientists and engineers would like to be certain that lightning characteristics so obtained also apply to lightning which strikes small buildings, power lines, missiles, etc. The Empire State Building study was the first to show that most of the flashes to a very tall structure are initiated by the structure itself. In the Lugano study about 75% of the flashes observed were initiated by the towers. These structure-initiated flashes differ significantly from the usual cloud-to-ground flash. Flashes to very tall structures which are not structure-initiated are thought to resemble the usual lightning to ground, but there is still some dispute about this.

It is appropriate now to look at how lightning gets started. The usual flash between cloud and ground is initiated in the base of the cloud. The initiating discharge, the downward-traveling spark shown in Fig. 2.1a,b, is called the *stepped leader*. The stepped leader is a low-luminosity traveling spark which moves from the cloud to the ground in rapid steps about 50 yards long. Each step takes less than a millionth of a second, and the time between steps is about 50 millionths of a second. The stepped leader is not seen by the eye, but may be photographed with special cameras (see Chapter 16, Fig. 16.3). The visible lightning flash discussed in the previous chapter occurs when the stepped leader contacts the ground. Precisely what happens when the stepped leader reaches the ground is the subject of Chapter 9. What is important to note now is that the usual stepped leader starts from the cloud without any "knowledge" of what buildings or geography are present below. In fact, it is thought, as suggested in Chapter 2, that the stepped leader is "unaware" of objects beneath it until it is some tens of yards from the eventual strike point. When "awareness" occurs, a traveling spark is initiated from the point to be struck and propagates upward to meet the downward-moving stepped leader, completing the path to ground. In this way the usual lightning flash to ground or to small structures is started. A small fraction of the strikes to very tall buildings also occurs in this way.

However, most lightning flashes to very tall buildings are the result of a reverse process. They are initiated by stepped leaders which start at the building top and propagate upward to the cloud. Because they propagate upward, they and the resulting visible discharge channel branch upward (Fig. 6.1). It is possible that upward-going leaders are just long versions of the leaders (previously called traveling sparks) which propagate upward some tens of yards from lightning rods. That is, the upward-moving stepped leaders from tall buildings may well contact downward-moving leaders beneath or within the cloud. On the other hand, the upward-moving stepped leaders may simply terminate in some region of cloud charge.

Lightning flashes initiated by tall buildings exhibit different current characteristics from those of the usual cloud-to-ground flash discussed in Chapter 5 and illustrated in Fig. 5.7. The current in a structure-initiated flash rises slowly, in hundredths or even tenths of a second, to a current peak of a few hundred amperes and flows for a few tenths of a second. Often the low-level continuous current is punctuated by one or more current peaks similar to those shown in Fig. 5.7 for strokes subsequent to the first. Sometimes the continuous current stops before a current peak occurs. These current peaks are generally larger than those which occur during the continuing current. More details of the characteristics of upward-moving lightning are given in Ref. 6.7.

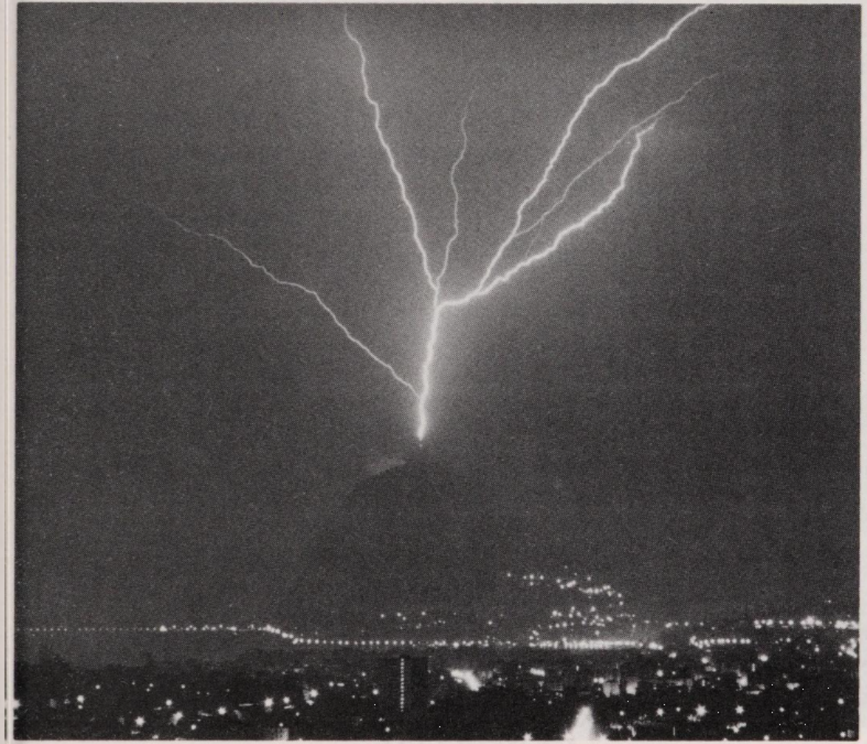

Fig. 6.1a. Lightning initiated by an upward-moving leader from a tower on Mt. San Salvatore near Lugano, Switzerland. The spot directly beneath the bottom of the lightning channel is a tower light. Upward-initiated lightning is branched upward in contrast to the downward branching of the usual cloud-to-ground lightning flash. (Courtesy, Richard E. Orville, State University of New York at Albany)

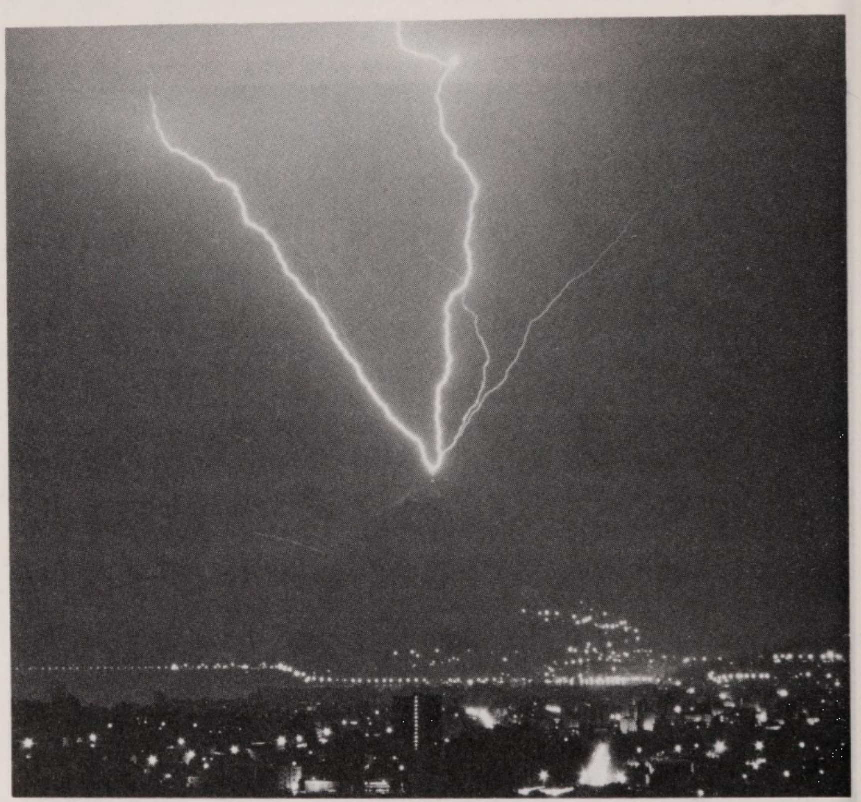

Fig. 6.1b. Lightning strikes twice! Another upward-going lightning from the San Salvatore tower. (Courtesy, Richard E. Orville)

It may appear logical from the content of this chapter that lightning should always "hit the tallest object". (Since the point of "strike" is determined by a leader which moves upward from the strike point, the strike point could just as well be called the "point of initiation".) Occasionally it doesn't! The Empire State Building has been struck 50 ft below the top (Ref. 6.2). The usual explanation for such anomalous behavior is the following: It is thought that the greater the electrical charge residing on the downward-moving stepped leader, the longer will be the connecting leader propagating upward from the building top. Thus, a relatively weak stepped leader can come closer to a building top without drawing an upward leader than can a relatively strong stepped leader. It is possible, therefore, that a weak stepped leader might "sneak" past the top of a building and only draw a leader when it had reached some lower level. Another explanation for the anomalous behavior could be that the obvious strike point has been kept from generating an upward-moving leader by a pocket of airborne charge, so-called *space charge.* Properly distributed regions of space charge could cause the lightning to strike almost anywhere. In any event, the cone of protection around the "highest point" (see Chapter 2) almost always describes the zone in which lightning will not strike.

chapter seven

How Are Thunderstorms Formed?

Are There Locations With No Lightning?

How Many Thunderstorms Are In Progress In The World At One Time?

Roughly 2000 thunderstorms are in progress in the world at any one time (Ref. 7.1). A typical storm is thought to produce one to three cloud-to-ground flashes each minute; and thus, considering all thunderstorms in progress, there are perhaps 30 to 100 flashes to ground every second (Refs. 7.1, 7.2). The statistics on the number of thunderstorms in progress in the world at any one time were obtained in the 1920s by examining the records of meteorological stations located around the world. Where there were no meteorological stations, estimates were made of the thunderstorm activity. For this reason the number 2000 may be somewhat in error. Further, estimates of the number of cloud-to-ground flashes per minute for a typical storm are based primarily on data obtained at relatively few locations throughout the world and may also be in error. For example, very little is known about the lightning or other properties of storms which occur in the tropical regions of South America and South Africa. With the help of orbiting satellites, a more accurate determination of world-wide thunderstorm activity is possible and will probably be made in the near future.

A *thunderstorm-day* for a given location is defined as a day on which thunder is heard at that location, independent of whether one or many thunders were heard. Thunder cannot usually be heard if the lightning causing it is more than about 15 miles away (see Chapter 12). In Fig. 7.1 and 7.2, thunderstorm-day maps are shown for the U.S. and the world, respectively. Each curved line represents a fixed and stated number of thunderstorm-days *per year* and is drawn through all geographical locations that have that particular number of thunderstorm-days. One of the most active regions on earth is Java where thunder is heard 223 days per year. In the U.S., central Florida has the highest number of thunderstorm-days per year with 90. The lowest number occurs along the Pacific coast region of northern California, Oregon, and Washington where thunderstorms and lightning are rare.

A more pertinent statistic than the number of thunderstorm-days per year is the number of lightning strikes per square mile per year. While it is relatively easy to determine thunderstorm days (one needs merely to listen), it is a more difficult task to determine accurately the number of strikes per square mile. The strikes per area have been determined (1) from photographs taken sequentially over periods of several years, (2) from records of strikes to power lines, and (3) from electrical lightning counters which respond to the radio waves emitted by lightning. The combined results of several studies indicate that the number of flashes to ground per square mile per year is equal to between 0.05 and 0.8 times the number of thunderstorm-days per year (Refs. 7.3, 7.4, 7.5). For example, if you live in a region of the U.S. with 40 thunderstorm-days per year, you can expect between 2

Fig. 7.1. The number of days per year on which thunder is heard at various locations in the U.S.A. Adapted from "Mean Number of Thunderstorm Days in the United States", Technical Paper No. 19, Climatological Services Division, Weather Bureau, September 1952.

and 30 strikes per year in a square mile area surrounding your home. A lightning strike within a square mile area produces thunder which is heard less than about 3 seconds after the flash (see Chapter 12). You might try to determine for yourself the number of thunderstorm-days and strikes per square mile occurring in your area each year.

As is evident from Figs. 7.1 and 7.2, some parts of the world have a great deal of lightning while others have essentially no lightning. The degree of thunderstorm activity in a particular geographical area depends on its prevailing meteorological conditions.

Thunderstorms can usually be classified as (1) local or convective, or (2) organized traveling. Local thunderstorms form independently of one another and have lifetimes of an hour or two. They produce moderate lightning activity, moderate winds, rain, and sometimes small hail. Most lightning research has been concerned with lightning produced by local thunderstorms because they are relatively easy to study. A local thunderstorm is shown in Fig. 7.3. Organized thunderstorms are violent storms. They may last for many hours producing severe lightning activity, hail over an inch in diameter, winds exceeding 60 mph, and sometimes tornadoes. Such storms are often associated with cold fronts. They may line up along fronts for distances of tens or even hundreds of miles and travel along with the fronts.

What conditions lead to the formation of thunderstorms, and how are those thunderstorms formed? Consider the local or convective thunderstorm. The conditions necessary for the formation of a local thunderstorm are: (1) the air from ground level to many thousands of feet must be moist, (2) the atmosphere must be "unstable" (defined in the next paragraph), and (3) the sun must heat the ground and the air near the ground. In an unstable atmosphere, hot, wet air near the ground will rise to heights where the temperature is below freezing, eventually forming a thundercloud. Let's look now at what is meant by an unstable atmosphere.

If a volume or *parcel* of air is to rise in the atmosphere, it must be lighter than the air which surrounds it. Hot air balloons rise because hot air is less dense (lighter) than normal air. (Helium filled balloons rise because helium is less dense than air.) For a parcel of warm air to continue rising, it must always be at a higher temperature than the surrounding air. Temperature decreases with altitude in the atmosphere, so that the warm air parcel from the ground might be expected to rise continuously. This is not necessarily the case, however, since as the parcel rises it encounters decreasing air pressure. As a result, the parcel expands, and the act of expansion causes the parcel to cool. If the water vapor in the air parcel does not condense, then the cooling rate as the parcel rises will be about 5.5°F per 1000 ft. The air temperature must decrease faster than this if the parcel is to keep moving upward. The air temperature does not often decrease this rapidly much above the earth's surface. Fortunately for the thunderstorm, if the air parcel is moist, water vapor will condense as the parcel rises, and the process of condensation releases heat into the parcel. A moist parcel of air will cool at about 3.3°F per 1000 ft of ascent. If the atmospheric temperature decreases faster than 3.3°F per 1000 ft, the atmosphere is said to be "unstable". The parcel will continue to rise.

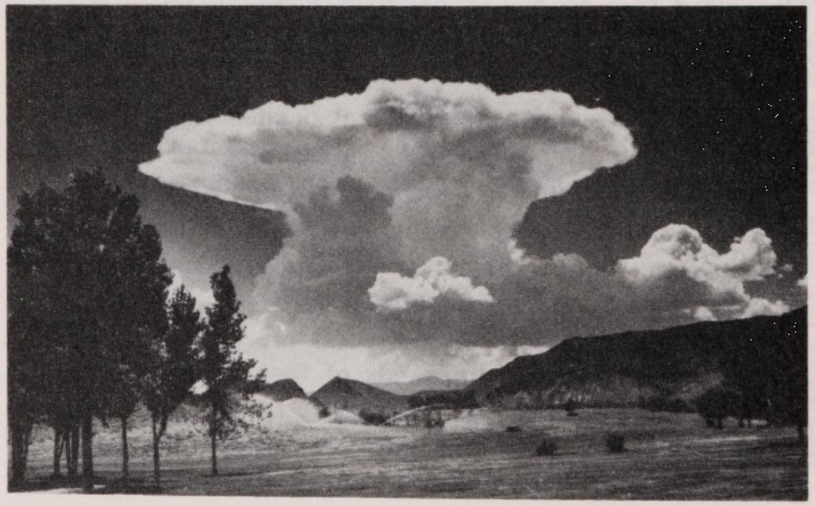

Fig. 7.3. A local or convective thunderstorm at Socorro, New Mexico. (Courtesy, Marx Brook, New Mexico Institute of Mines and Technology)

There are three stages in the life of a local or convective thundercloud: cumulus, mature, and dissipating. The cumulus stage begins when small, fluffy white, cumulus clouds form from rising air parcels. In time, many cumulus clouds combine to form a larger cloud, a cumulus congestus, perhaps a mile in diameter, with a well-defined top which rises at 1000 to 2000 ft per minute. The primary characteristic of the cumulus stage is that air motion throughout the cloud is upward. The cumulus stage lasts 10 to 15 minutes. As the cumulus congestus cloud grows, water drops and ice form within the cloud. Eventually the rain, hail, and snow within the cloud become sufficiently heavy that they can no longer be moved upward by the prevailing updrafts.

The formation of heavy precipitation signals the beginning of the mature stage. Precipitation begins to fall, dragging air downward with it. The cloud, now a cumulonimbus, contains both updrafts and downdrafts, and rain from the cloud reaches the ground. The top of a mature thundercloud may extend to 60,000 ft. It flattens out and assumes a characteristic anvil shape on reaching the stratosphere, the region of the atmosphere in which temperature is constant or increases with height. The mature stage of the storm lasts 15 to 30 minutes and is accompanied by considerable lightning activity. Finally the storm enters its dissipating stage. The violent updrafts and downdrafts decrease, and precipitation is less intense. The water droplets in the cloud evaporate, and the remainder of the cloud is blown away. The dissipating stage lasts about 30 minutes. The total lifetime of the convective thundercloud is roughly an hour.

A single convective thundercloud is technically referred to as a *cell.* Before one thundercloud cell has dissipated others may form. If the various cells form in close proximity, it may be impossible to distinguish between them from the ground. The result is a total storm of relatively long time duration and with relatively constant lightning activity – actually the combined result of the life cycles of many cells. An average local thunderstorm incorporates perhaps three thundercloud cells. Each is electrically active for about 15 to 30 minutes (during its mature stage) and, if the electrically active periods of the three cells do not overlap much, the storm produces appreciable lightning for about an hour and has a total duration of about two hours.

We look now at the traveling organized thunderstorms which produce severe weather. Typically, lines of severe thunderstorms are formed near the boundary of a moving cold front and stationary warm moist air. The cold front, a large mass of cold air, pushes beneath the warm moist air and forces it to rise. The rising air creates thunderstorms along the front. For the forming thunderstorms to become severe, the meteorological conditions must usually differ somewhat from those during the formation of local thunderstorms. Prior to the formation of severe thunderstorms there is often a warm dry layer of air aloft (and a region in which temperature increases with height) which tends to hold down the warm moist air near the earth's surface. The air near the ground becomes progressively warmer and more humid. When the cold front causes the warm air to rise, the ability of the dry air to hold down the wet is destroyed and thunderclouds are violently formed. It should be pointed out that sometimes severe thunderstorms occur under conditions that would normally lead to the generation of only local thunderstorms. There is some argument as to whether severe thunderstorms are composed of many individual cells each similar to a convective thundercloud cell or whether the structure of a severe storm is basically different. It appears now that some severe storms are composed of many individual cells each with a fairly well-defined life cycle while other severe storms do not fit this pattern at all.

One of the primary characteristics of the organized storms is that they can propagate themselves. There are several views of how the propagation process takes place. Common to most theories is the idea that cold air brought to ground by downdrafts through a given thundercloud spreads outward and forces warm moist air adjacent to that thundercloud upward generating a new thundercloud. It appears also that in order for severe storms to propagate effectively over long distances it is usually necessary for the winds aloft to be relatively strong and to increase with height. An excellent non-technical description of what is known about traveling thunderstorms, as well as what is known about local thunderstorms, is given in the paperback book *The Thunderstorm* written by L. J. Battan of the University of Arizona (see References).

chapter eight

Does Cloud Lightning Differ From Cloud-to-Ground Lightning? Which Is More Common?

Does Lightning Occur Only In Thunderstorms?

There are two principal types of lightning discharges – flashes which occur between the thundercloud and the earth (cloud-to-ground discharges) and flashes within the thundercloud (intracloud discharges). Other types of discharges such as cloud-to-cloud lightning and cloud-to-air lightning also occur but not very frequently. It is a widespread misconception that cloud-to-cloud lightning is common.

Although the thundercloud is the most common source of lightning, it is not the only one. Lightning occurs in snowstorms, in sandstorms, in non-thunderstorm rain and ice (see Chapter 4), in the ejected material above erupting volcanoes (Ref. 8.1; Fig. 8.1), near the fireballs created by nuclear explosions (Fig. 8.2), and apparently even out of the clear blue sky (giving rise to the expression "a bolt from the blue"). For lightning to occur, a region of the atmosphere must attain an electrical charge sufficiently large to cause electrical breakdown of the air. Some charging almost always occurs when any particulate matter (for example, dust or sand) is subjected to strong winds. (An obvious parallel to the frictional charging discussed in Chapter 1.) Within a typical thundercloud a turmoil of wind, water, and ice exists in the presence of a temperature which decreases with height. Small particles are carried upward by the wind; large particles move downward under the dominant influence of gravity. The various ascending and descending particles exhibit different velocities depending on their size. Particles that move at different velocities collide with one another, and out of these interactions, in ways not yet fully understood, emerge light,

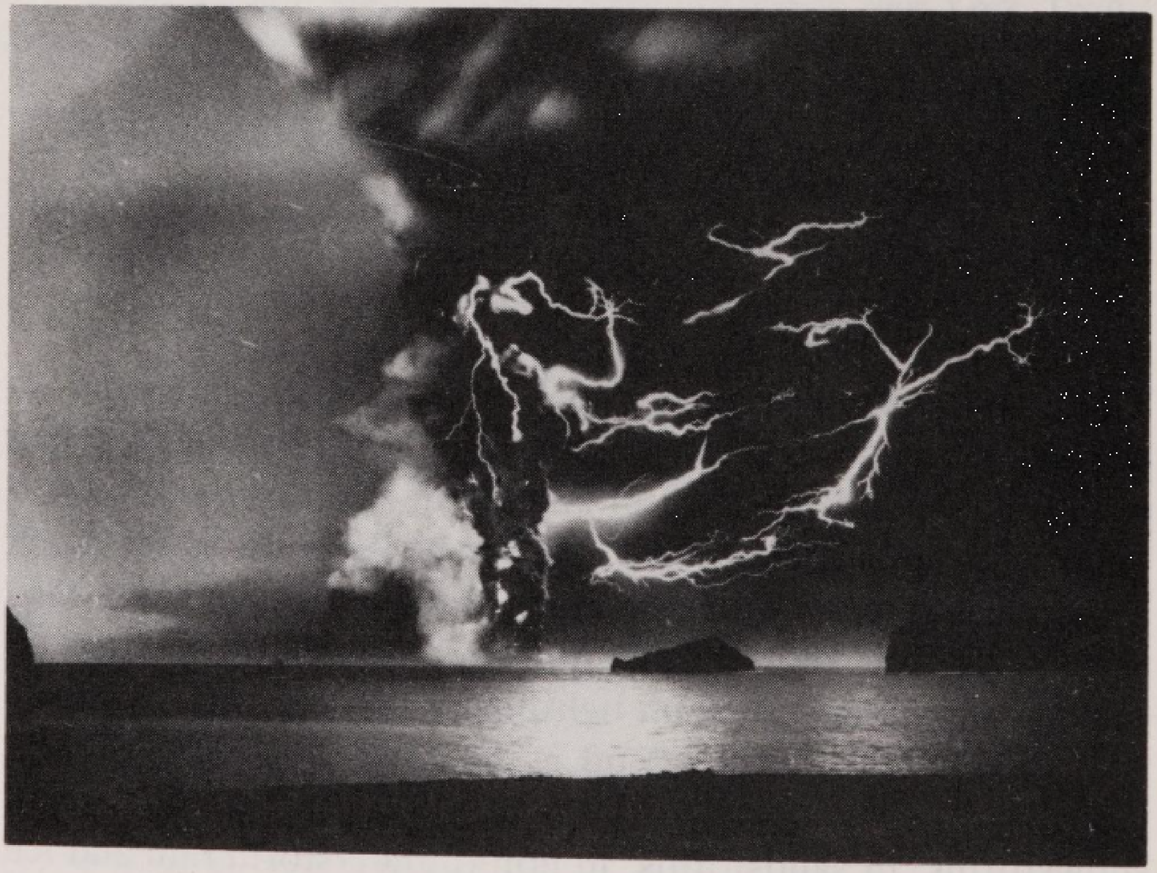

Fig. 8.1. Lightning in the volcano cloud over Surtsey, near Iceland, in December 1963. Volcanic eruptions were observed on November 14, 1963 off the southern coast of Iceland in water about 130 yards deep. Within 10 days an island over half a mile long and about 100 yards above sea level was formed. The island was named Surtsey by the Icelandic Government. (Courtesy, Sigurgeir Jónasson, Icelandair)

positively-charged particles which move upward and heavy, negatively-charged particles which move downward.

The probable distribution of cloud charge for a typical South African thundercloud cell is shown in Fig. 8.3 (Ref. 8.2). The upper part of the thundercloud carries a preponderance of positive (+) charge while the lower part carries a net negative (–) charge. The primary region of positive charge is referred to as the P-region, the primary region of

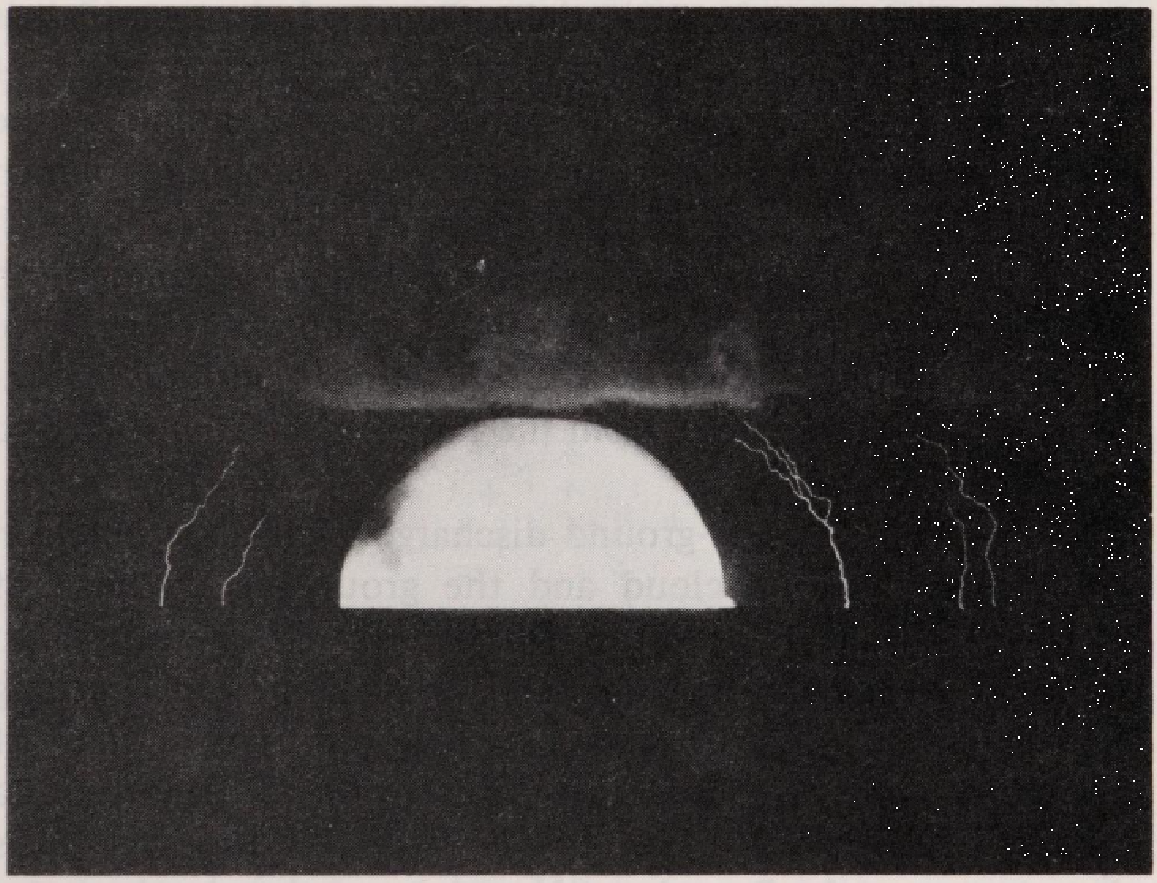

Fig. 8.2. Five lightning flashes induced by an experimental thermonuclear device exploded on October 31, 1952, at Eniwetok in the Pacific. Photograph is frame number 72 (detonation occurs in frame 1) of a 2000 frame-per-second movie taken from 20 miles away. The five flashes were initiated immediately after detonation probably from instrument bunkers projecting above sea level and propagated upward similar to typical flashes from tall buildings (see Chapter 6). All flashes lasted almost one-tenth of a second and apparently none contained subsequent strokes. The tops of the lightning channels bend towards the fireball. Fleecy cumulus clouds are visible with bases at 2000 ft. The clouds were not lightning producers. (Courtesy, U.S. Atomic Energy Commission)

negative charge the N-region. Recent research indicates that the N-region is not necessarily the vertical pillar of negative charge shown in Fig. 8.3, but rather may be a pillar which leans at an appreciable angle from the vertical (Ref. 8.3). In addition to the main cloud charges (P and N), there may be a small pocket of positive charge at the base of the thundercloud (the p-region). Exact values of the charges in the P-, N-, and p-regions are still a matter of controversy. Malan (Ref. 8.2) suggests P = +40 coulombs, N = -40 coulombs, p = +10 coulombs. (One coulomb is the amount of charge which is moved past a given cross-section of a wire when a current of 1 amp flows for 1 second.) Whatever the exact numbers, the charge in the cloud must be more than the charge which flows in the lightning channel since it is the cloud which provides the charge for the channel. A typical lightning flash to ground generally lowers about 25 coulombs of negative charge from the N-region of the cloud to ground. Occasionally discharges occur from the P-region or the p-region to ground.

The typical cloud-to-ground discharge takes place between the N-region of the cloud and the ground, a distance of roughly two miles. Often the cloud-to-ground lightning path occurs in clear (rain-free) air. The cloud-to-ground lightning flash is, as noted in Chapter 5, composed of a number of discrete strokes, the total time duration of the flash being a few tenths of a second. The typical intracloud discharge takes place between the P- and the N-regions of the cloud, over a distance of a mile or two. The discharge path is through ice and supercooled water (water below 32°F which is not frozen) since most of a typical thundercloud is at a temperature below the freezing level. While the total time duration, charge transfer, and length of an intracloud discharge are similar to that of a cloud-to-ground discharge, the discharge processes differ. This is so because of the different environments in which the two discharges occur and

because the cloud-to-ground discharge terminates on a conductor (the earth) while the intracloud discharge does not. Instead of being composed of a number of discrete current and light pulses (strokes), the typical intracloud discharge is fundamentally composed of a single slowly-moving spark or leader which bridges the gap between the N- and P-regions in a few tenths of a second. There is controversy as to whether the leader moves up from the N-region and carries negative charge or moves down from the P-region and carries positive charge. Each may in fact occur on different occasions. A low and continuous luminosity is

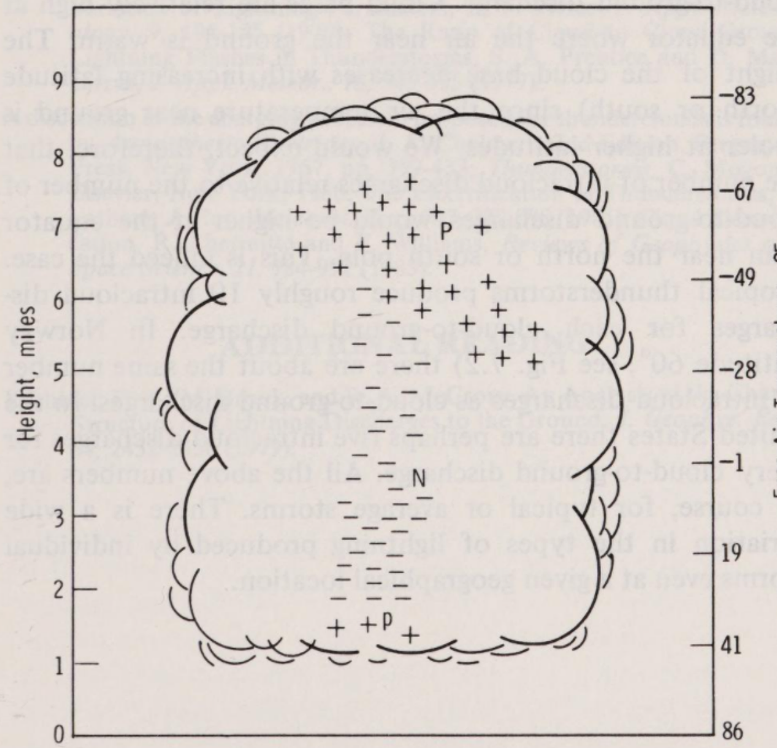

Fig. 8.3. Probable distribution of thundercloud charge according to D. J. Malan (Ref. 8.2).

observed in the cloud during the leader propagation. Superimposed on the continuous luminosity are a number of luminous pulses each lasting about a thousandth of a second. It is thought that these pulses, called K-changes, occur when the propagating leader contacts a pocket of charge opposite in polarity to that of the leader. Much more is known about cloud-to-ground discharges than about intracloud discharges: it is impossible to photograph adequately the intracloud discharge channel since it is obscured by the cloud.

The base of the N-region of a thundercloud is generally situated at the height at which freezing occurs (32°F). The closer the N-region is to ground, the more likely is a cloud-to-ground discharge. Cloud bases are relatively high at the equator where the air near the ground is warm. The height of the cloud base decreases with increasing latitude (north or south) since the air temperature near ground is cooler at higher latitudes. We would expect, therefore, that the number of intracloud discharges relative to the number of cloud-to-ground discharges would be higher at the equator than near the north or south pole. This is indeed the case. Tropical thunderstorms produce roughly 10 intracloud discharges for each cloud-to-ground discharge. In Norway (latitude 60°; see Fig. 7.2) there are about the same number of intracloud discharges as cloud-to-ground discharges. In the United States there are perhaps five intracloud discharges for every cloud-to-ground discharge. All the above numbers are, of course, for typical or average storms. There is a wide variation in the types of lightning produced by individual storms even at a given geographical location.

chapter nine

Does A Stroke Between Cloud And Ground Travel Upwards or Downwards?

The answer to the question "Does lightning between cloud and ground go upwards or downwards?" is that, in a sense, it does both. The usual lightning flash between cloud and ground (excluding the discharges initiated by tall structures discussed in Chapter 6) begins with a visually-undetected downward-moving traveling spark called the stepped leader (see Chapters 2 and 6). Since the lightning flash begins with a downward-moving discharge, lightning moves from the cloud to the ground. On the other hand, when the stepped leader reaches ground (or is contacted by an upward-moving discharge some tens of yards above the ground) the leader channel first becomes highly luminous at the ground and then at higher and higher altitudes. The bright, visible channel, or so-called *return stroke,* is formed from the ground up, and one could say, therefore, that visible lightning moves from the ground to the cloud.

It is thought by most lightning researchers that the usual cloud-to-ground discharge begins as a local discharge between the p-charge region in the cloud base and the N-charge region above it (Fig. 9.1, see also Fig. 8.3). This discharge frees *electrons* in the N-region previously immobilized by attachment to water or ice particles. (Electrons are fundamental particles which carry the smallest known unit of negative electrical charge.) Because of their small mass, free electrons are extremely mobile compared to air atoms or to charged ice or water particles. The free electrons overrun the p-region, neutralizing its small positive charge, and then continue their trip toward ground. The vehicle for moving the negative charge to earth is the stepped leader.

Exactly how the stepped leader works is not understood. What is known is that it moves from cloud to ground in rapid luminous steps about 50 yards long. In Figs. 9.1 and 9.2 the luminous steps appear as darkened tips on the less-luminous leader channel which extends upward into the cloud. Each leader step occurs in less than a millionth of a second. The time between steps is about 50 millionths of a second. Negative charge is continuously lowered from the N-region of the cloud into the leader channel. The average velocity of the stepped leader during its trip toward ground is about 75 miles per second with the result that the trip between cloud and ground takes about 20 thousandths of a second. A typical stepped leader has about 5 coulombs of negative charge distributed over its length when it is near ground. To establish this charge on the leader channel an average current of about 100 or 200 amperes must flow during the whole leader process. The pulsed currents which flow at the time of the leader steps probably have a peak current of about 1000 amperes. The luminous diameter of the stepped leader has been measured photographically to be between 1 and 10 yards. It is thought that most of the stepped-leader current flows down a narrow conducting core less than an inch in diameter at the center of the observed leader. The large photographed diameter is probably due to a luminous electrical corona surrounding the conducting core.

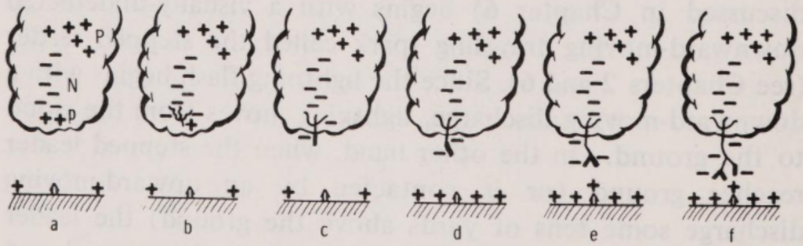

Fig. 9.1. Stepped leader initiation and propagation. (a) Cloud charge distribution just prior to p-N discharge. (b) p-N discharge. (c)-(f) Stepped leader moving toward ground in 50-yard steps. Time between steps is about 50 millionths of a second. Scale of drawing is distorted for illustrative purposes.

When the stepped leader is near ground, its relatively large negative charge induces large amounts of positive charge on the earth beneath it and especially on objects projecting above the earth's surface (Fig. 9.2). Since opposite charges attract each other, the large positive charge attempts to join the large negative charge, and in doing so initiates upward-going discharges (Figs. 2.1 and 9.2). One of these upward-

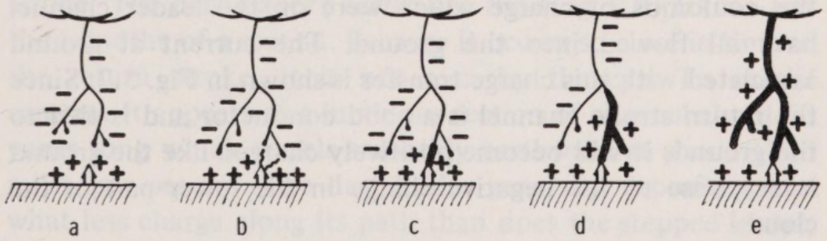

Fig. 9.2. Return stroke initiation and propagation. (a) Final stages of stepped leader descent. (b) Initiation of upward-moving discharges to meet downward-moving leader. (c)-(e) Return stroke propagation from ground to cloud. Return stroke propagation time is about 100 millionths of a second; propagation is continuous. Scale of drawing is distorted.

going discharges contacts the downward-moving leader and thereby determines the lightning strike-point. When the leader is attached to ground, negative charges at the bottom of the channel move violently to ground, causing large currents to flow at ground and causing the channel near ground to become very luminous. Since electrical signals (or any signals, for that matter) have a maximum speed of 186,000 miles per second – the speed of light – the leader channel above ground has no way of knowing for a short time that the leader bottom has touched ground and has become highly luminous. The channel luminosity, the return stroke, propagates continuously up the channel and out the channel branches at a velocity somewhere between 20,000 and 60,000 miles per second, as shown in Fig. 9.2. The trip between ground and cloud takes about 100 millionths of a second. As the return stroke luminosity moves upward so also does the region of high current. When the leader initially touches ground, copious numbers of electrons flow to ground from the channel base. As the return stroke moves upward, large numbers of electrons flow at greater and greater heights. Electrons at all points in the channel *always move downward* even though the region of high current and high luminosity moves upward. Eventually, in some thousandths of a second, the coulombs of charge which were on the leader channel have all flowed into the ground. The current at ground associated with this charge transfer is shown in Fig. 5.7. Since the return stroke channel is a good conductor and is tied to the ground, it will become positively charged like the ground in response to the negative charge in the lower part of the cloud.

It is the return stroke that produces the bright channel of high temperature (Chapter 11) that we see. The eye is not fast enough to resolve the propagation of the return stroke and it seems as if all points on the channel become bright simultaneously. The reason we do not visually detect the stepped leader preceding a first return stroke is because the eye cannot resolve the time between when the weakly luminous leader is formed and the bright return stroke illuminates the leader channel. The return stroke produces most of the thunder we hear (see Chapter 12).

After the stroke current has ceased to flow, the lightning flash may be ended, in which case the discharge is called a single-stroke flash. As noted in Chapter 5, most flashes contain three or four strokes, typically separated by gaps of 40 or 50 thousandths of a second. Strokes subsequent to the first are initiated only if additional charge is made available to the top of the previous stroke channel less than about 100 thousandths of a second after current has stopped flowing in the previous stroke. Additional charge can be made available to the channel top by the action of electrical discharges (so called *K-streamers* and *J-streamers*) which move upward from the top of the previous return stroke into higher areas of the N-charge region of the cloud (Fig. 9.3). When this additional charge is available, a continuous (as opposed to stepped) leader, known as a *dart leader*, moves down the defunct return stroke channel again depositing negative charge from the N-region along the channel length. The dart leader thus sets the stage for the second (or any subsequent) return stroke. The dart leader's earthward trip (Fig. 9.4) takes a few thousandths of a second. Because it occurs so close in time to the return stroke, it is not seen by the eye. To special cameras it appears as a luminous section of channel about 50 yards long which travels smoothly earthward at about 1000 miles per second. The dart leader generally deposits somewhat less charge along its path than does the stepped leader, with the result that subsequent return strokes generally lower less charge to ground and have smaller currents (Fig. 5.7) than first strokes.

The first stroke in a flash is usually strongly branched downward because the stepped leader is strongly branched

(Figs. 9.1 and 9.2). Dart leaders generally follow only the main channel of the previous stroke and hence subsequent strokes show little branching (Fig. 9.4).

The time between strokes which follow the same path can be tenths of a second if a continuing current (Chapter 5) flows in the channel between strokes. Apparently, the channel is ripe for a dart leader only after the continuing current has terminated.

A typical cloud-to-ground discharge lowers about 25 coulombs of negative charge from the N-region of the cloud to the earth. This charge is transferred in a few tenths of a second by the three or four component strokes and any continuing current which may flow. While the leader-return stroke process transfers charge to ground in two steps (charge is put on the leader channel and then is discharged to ground), the continuing current represents a relatively steady charge flow between the N-region and ground.

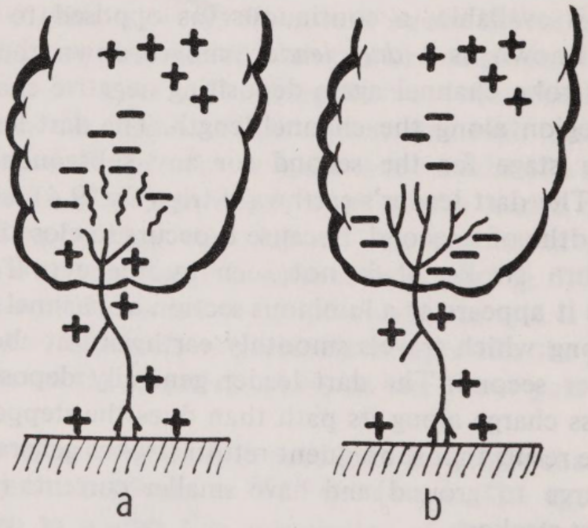

Fig. 9.3. K-streamers and J-streamers making more negative charge available to the channel top during the 50 thousandths of a second or so following the cessation of current flow in the first return stroke. Scale of drawing is distorted.

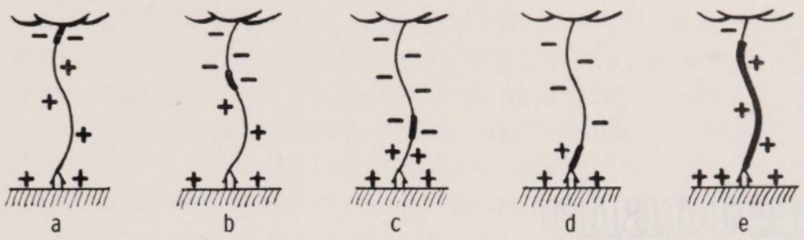

Fig. 9.4. Dart leader and subsequent return stroke. (a)-(c) Dart leader deposits negative charge on defunct first-stroke channel during its thousandth-of-a-second trip to ground. (d)-(e) Subsequent return stroke propagates from ground to cloud in about 100 millionths of a second. Scale of drawing is distorted.

Thus far in this chapter we have discussed the usual stepped leader which lowers negative charge between the cloud and the earth. Occasionally downward-moving stepped leaders are observed that lower positive charge. Currents due to the resulting "positive" return strokes have been measured directly during discharges to instrumented towers. Positive strokes are characterized by rates-of-rise of current at the ground roughly five times slower than those for typical negative strokes, and by charge transfers roughly three times greater than those of typical negative strokes. The maximum measured charge transfer due to a positive stroke is 300 coulombs. Positive strokes are probably initiated between the P-charge region of the cloud and ground when strong winds blow the cloud such that the P-region is brought relatively close to a mountain side or to the earth's surface. Positive discharges rarely consist of more than one stroke.

chapter ten

How Long And How Wide Is The Lightning Channel?

Why Is Lightning Zig-Zag?

How Can I Best Photograph Lightning?

Let's begin with "how long". Channels longer than 90 miles have been observed (Ref. 10.1). On the other hand, sparks of a few yards length have been seen in and around clouds, and probably even shorter "lightning" exists.

There are basically four ways of determining channel length. (1) The most straightforward way is by photographing lightning and then determining its length from the photograph. Since channels inside clouds cannot be photographed, the value of this technique for determining channel length is somewhat restricted. (2) Radar has been used to measure channel length. A radar set sends out electromagnetic pulses which are reflected back by certain objects (e.g., metallic airplanes). Since the pulses travel at 186,000 miles per second, measuring the elapsed time between the emission of a pulse and the reception of its reflection enables the distance to the reflector to be measured. An actual radar set has a TV-like screen on which appears images of the reflecting objects. A lightning channel is a good conductor and hence reflects radar pulses much as an airplane does. Radar wavelengths can be chosen to minimize reflection of radar pulses by the ice and water in clouds so that a good image of the lightning channel can be obtained on the radar screen. (3) Channel lengths can be determined from the duration of thunder. The minimum possible channel length associated with a thunder duration of T seconds is roughly T/5 miles (see Chapter 12). For example, if thunder lasts 20 seconds, the channel producing it has a length of about 4 miles or more. (4) Finally, there are a number of ways of determining lightning channel height within a cloud from electrical measurements made on the ground (Ref. 10.2). Charge motion in the lightning channel or in the cloud will induce voltages and currents in ground-based instruments enabling properties of the channel and cloud charge to be determined. For example, the vertical height of the J-streamers and K-streamers occurring in the cloud between strokes (Fig. 9.3) can be determined from electrical measurements made at ground.

Now that we know how channel lengths are measured, let's look at the results of the measurements. The average vertical stroke height is about 3 to 4 miles. The maximum vertical extent of the usual stroke to ground is the top of the N-charge region, a height of 6 miles or more. Each stroke in a multiple-stroke flash averages about a third of a mile longer than the preceding one. This is the case because, in order to obtain negative charge for a new stroke, J-streamers and K-streamers tap new areas of the N-charge region of the cloud (Figs. 8.3 and 9.3) during the time between strokes, and these tapped regions become part of the new stroke. The horizontal component of the lightning channel within a cloud or through several clouds may be larger than the vertical component. Horizontal sections of 5 to 10 miles within clouds are not uncommon. Radar studies have shown horizontal channels longer than 90 miles (Ref. 10.1). Long horizontal channels must feed on the charge of many thundercloud cells. In addition to cloud-to-ground discharges with long horizontal in-cloud components or similar long intracloud or cloud-to-cloud discharges which do not reach ground, long lightning discharges have occasionally been observed to occur from the tops of thunderclouds upward (Ref. 10.2). These vertical air discharges may be tens of miles in length.

When we speak of the length of lightning, we normally picture long sections of the channel as being fairly straight. Photographs show, however, that the channel is very tortuous on almost any scale. There are zigs and zags 100 yards long and, within these, other zigs and zags 10 yards long, and within these yet smaller zigs and zags (Refs. 10.3, 10.4, 10.5). Very detailed photographs have shown lightning channels that twist and bend on a distance scale measured in inches (Ref. 10.5). Figure 10.1 shows a section of a lightning channel with a height of about 1000 yards; Fig. 10.2 shows about 200 yards of channel; Fig. 10.3 about 10 yards. If we could grab a long section of the channel and pull on both ends to straighten it out, the channel section might well be two or more times longer than we initially thought.

Lightning diameter measurements have been made in two ways: (1) by examining the interaction between lightning and objects and (2) from photographs. Photographic measurements of lightning almost always overestimate the luminous diameter of the channel: the bright channel overexposes the film making the recorded image broader than it should be. It is extremely difficult to expose a lightning channel photograph properly. The best channel diameter photographs (Ref. 10.5) yield diameters of between about 2 and 7 in., and these values are probably overestimates. Lightning photography is discussed again at the end of this chapter.

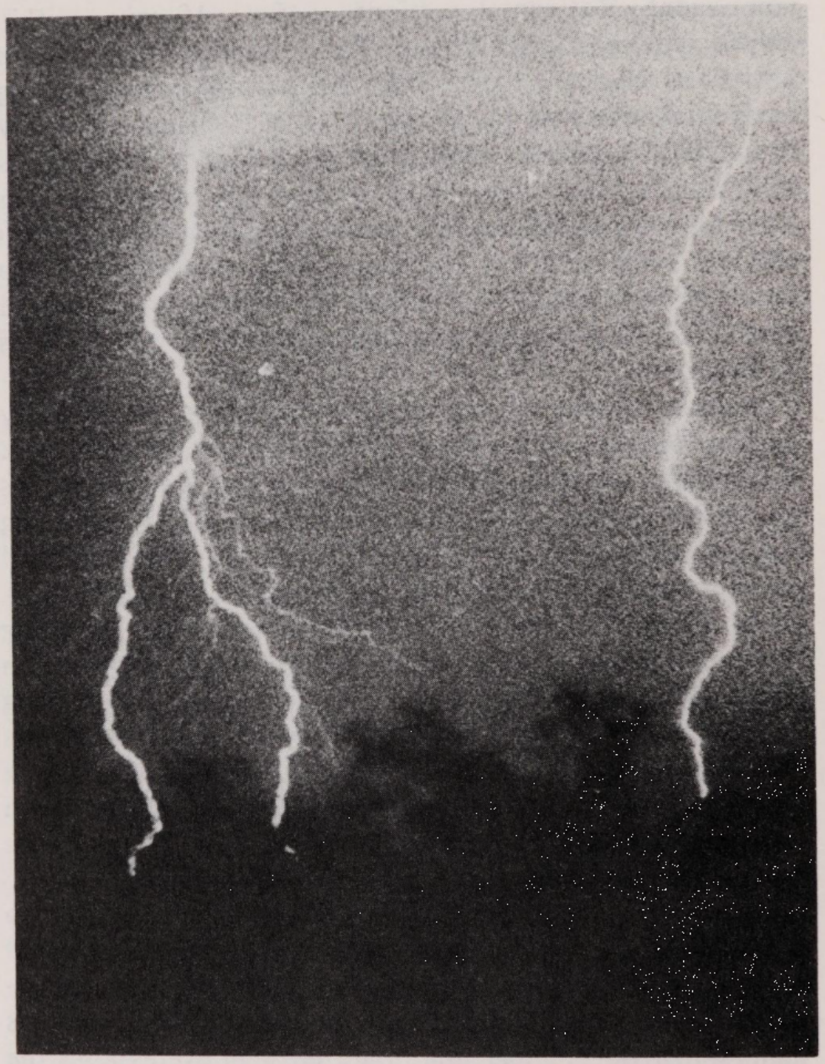

Fig. 10.1. About 1000 vertical yards of lightning channel near Tucson, Arizona (Ref. 10.4). Note the large scale channel tortuosity. (Courtesy, H. B. Garrett and A. A. Few, Rice University)

When lightning hits an object such as a tree or a rock, it leaves visible damage. In many cases the damage can be related to channel diameter. Taylor (Ref. 10.6; see also Chapter 5) found that the lightning-caused furrows that spiral along tree trunks are between about 0.6 and 5.0 in. wide. The lightning diameter, therefore, must be roughly this size or smaller. If it were much bigger, it is hard to see how it could create the furrows.

When lightning strikes sand or certain kinds of rocks, the channel heat melts the material along its path. When the melted material solidifies, the resulting *fulgurite* (from the Latin *fulgur*, meaning lightning) represents a permanent record of the lightning diameter and path. Fulgurites in dry

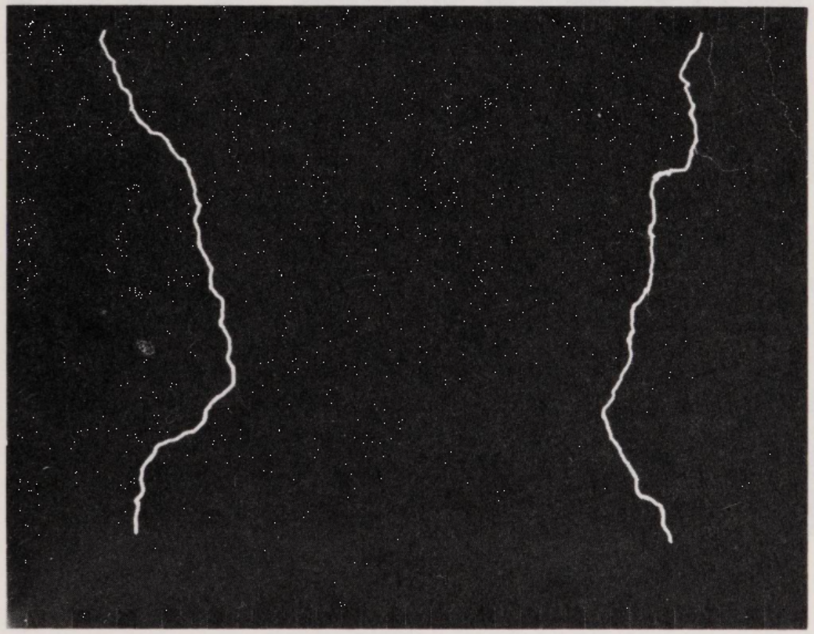

Fig. 10.2. Bottom portion of the split channel shown in Figure 10.1 (Ref. 10.4). Vertical height shown is about 200 yards. Tortuosity on a scale smaller than 10 yards is evident. (Courtesy, Leon E. Salanave, University of Arizona)

sand are generally long hollow tubes with corrugated glassy walls. An artificial fulgurite produced by an electrical discharge in the laboratory is shown in Fig. 10.4. Fulgurites have been traced downwards into sand as much as 20 yards. Diameters are usually 0.5 to 2 in. From the corrugated appearance of fulgurite walls, it is probable that the initial diameter collapses somewhat on cooling. "Fossil" fulgurites 250 million years old have been discovered (Ref. 10.7). The

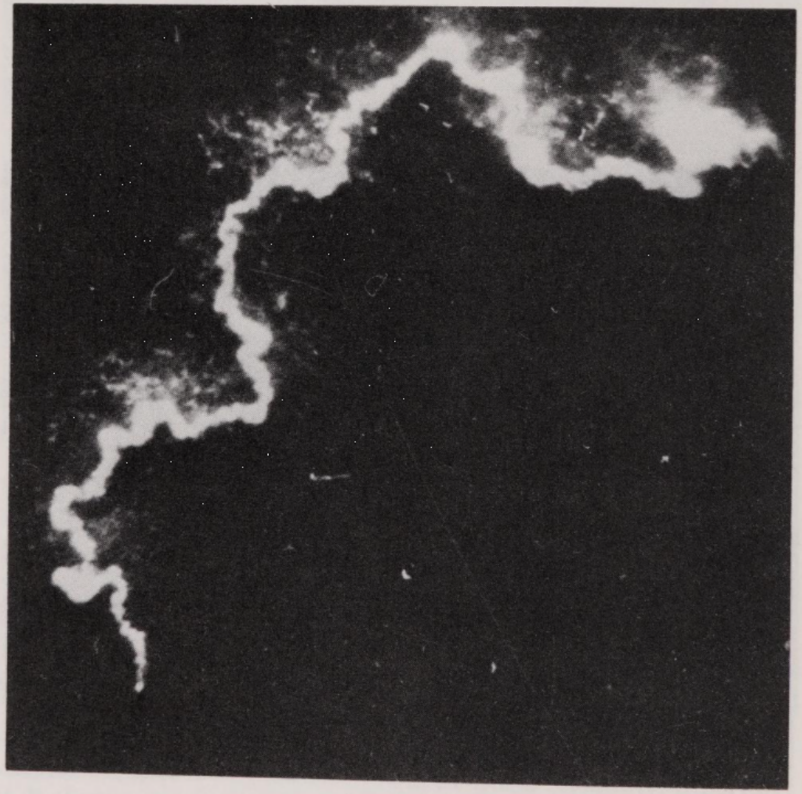

Fig. 10.3. One frame from a high-speed movie of lightning striking a TV tower near Tucson, Arizona (Ref. 10.5). About 10 yards of channel are shown and tortuosity on an inch scale is evident. (Courtesy, W. H. Evans, University of Arizona, and R. L. Walker, University of Florida, Cape Canaveral)

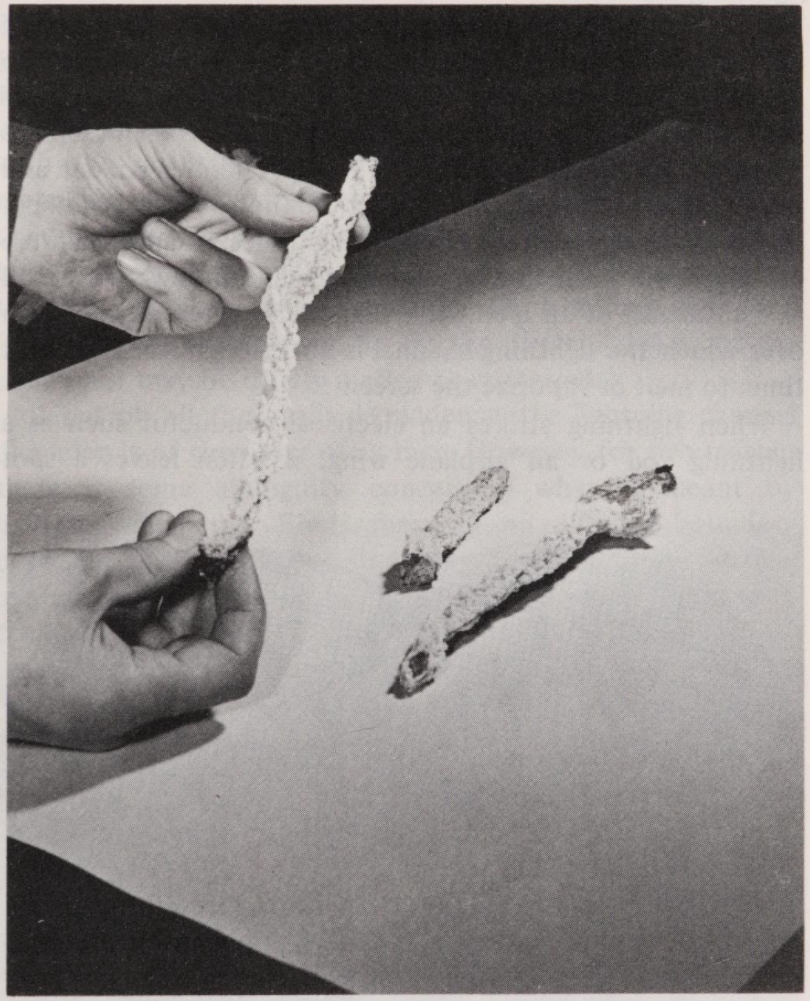

Fig. 10.4. Artificial fulgurites produced by P. L. Bellaschi, Westinghouse Electric Corporation, by allowing an electrical discharge to pass through quartz sand. The hollow tubes of solidified sand are close replicas of natural fulgurites.

fulgurite diameter probably does not differ much from the lightning diameter.

The author has measured lightning diameters by allowing lightning to pass through Fiberglas screens on the way to lightning rods and then measuring the size of the holes melted in the screen by the lightning (Ref. 10.8). The screens covered rods on the tops of towers near Tucson, Arizona and near Lugano, Switzerland. About 50 holes were obtained. Figure 10.5 shows typical lightning holes. Diameters were usually about an inch or smaller and sometimes were as small as a sixteenth of an inch. Hole diameters represent the width over which the lightning channel is hot enough for sufficient time to melt or vaporize the screen.

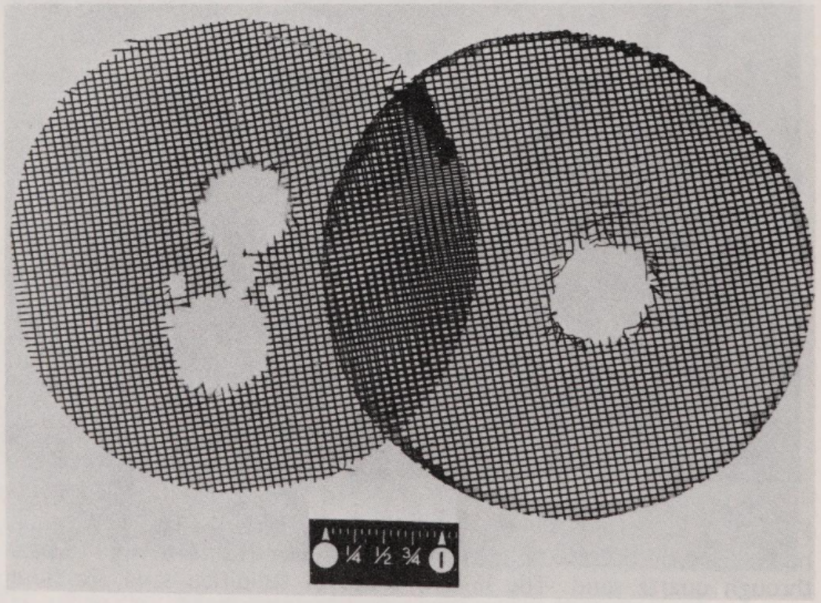

Fig. 10.5. Holes melted in two Fiberglas screens by lightning. At least four strokes passed through the screen on the left. One stroke passed through the screen on the right.

When lightning strikes an electrical conductor such as a lightning rod or an airplane wing, it often leaves a spot

(sometimes a raised lump, sometimes a depression) about an eighth of an inch wide. Examples of such spots on three copper disks are shown in Fig. 10.6. The size of a lightning spot is roughly the diameter of the lightning channel when it enters the conductor. At the contact point the lightning current must flow through a mixture of metal vapor and air, with the result that its diameter is smaller than in the metal-free air away from the conductor. Thus, spot sizes on conductors provide a lower diameter limit. It should be noted that a large lightning current flowing for a relatively long time may do considerably more damage to a conductor than just a spot. A hole may be burned (Figs. 4.1-4.3) or the conductor may be totally melted or vaporized.

Based on all the available evidence, the lightning channel diameter is of the order of an inch. However, for two reasons there is some ambiguity concerning what is meant by lightning diameter. First, there is no definite boundary between the stroke and the air surrounding the stroke; second, the diameter must change with time in response to the changing current.

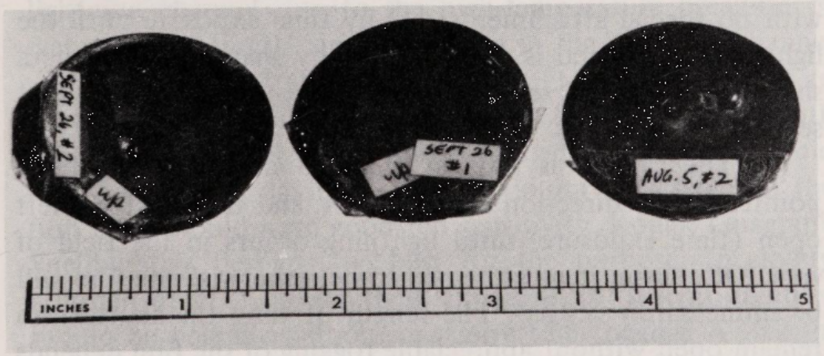

Fig. 10.6. Spots produced by lightning strikes to three copper disks which were placed on top of TV towers near Tucson, Arizona. The center disk was apparently hit by three lightning strokes, one of which raised a one-eighth inch lump. The disk on the right exhibits a copper lump apparently formed as the lightning channel moved back and forth across the disk.

Why is the lightning channel so tortuous? The answer is not known, but some reasonable guesses may be made. The larger-scale tortuosity in the channel (representing, say, tens of yards or more) is due to the fact that the stepped leader makes such an errant trip to ground. Why does it do this? Possibly various airborne regions of charge (space charge, see Chapter 6) divert the leader on its trip. More likely, the leader just doesn't know exactly where it wants to go, except that ultimately it wants to move downward. The smaller-scale tortuosity in the channel may be formed when the leader steps are formed, or may be formed by action of the magnetic forces associated with the return stroke current. As is probably becoming more and more apparent with each succeeding chapter in this book, there is an awful lot we still don't know about lightning.

Since we have discussed in this chapter the use of photography as a scientific tool to determine lightning channel parameters, it is appropriate to say a few words about how to take lightning photographs. There are basically two ways to photograph lightning using ordinary cameras with no special attachments: (1) by time exposure until the lightning occurs and is over, and (2) by snapping the camera shutter (set at 1/30 sec or slower) when the lightning is first seen.

(1) The camera is put on a tripod or other firm base, pointed in the direction of the storm, and the shutter is left open (time exposure) until lightning occurs in the field of view. Of course, it must be nighttime, otherwise the film will be immediately fogged. The length of time the shutter can remain open without appreciable fogging of the film depends on the ambient light level. Away from city lights with a film speed of ASA-100 (roughly the speed of Kodak Plus-X black and white film or Kodacolor-X color film) and an aperture opening of f/11, several minutes are possible. Camera focus should be set at infinity. Since there are several lightning strokes to ground during each minute of the electrically active period of a storm (Chapter 7), it is not difficult to obtain photographs. (2) If the lightning flash to be photographed consists of only one stroke, your reflexes will not be fast enough to fire the shutter in time to record the flash. However, if it is a multiple-stroke flash, as most flashes are, you will record a subsequent stroke or strokes. Since subsequent strokes occur at intervals of roughly 1/20 of a second, a shutter speed of 1/30 second or slower is necessary to avoid taking a picture of what goes on between strokes. Since subsequent strokes are generally unbranched (Chapter 9), the photographed lightning will be unbranched and will look somewhat peculiar. Again, for a film speed of ASA-100 try an aperture of f/11 with the focus set at infinity.

The two basic techniques for photographing lightning can be improved by using special equipment with ordinary cameras. (1) Time exposures of lightning in daylight are possible if the proper filter is used (Refs. 10.9, 10.10). Light from the sun is weak at a wavelength of 6563Å* (in the red) because hydrogen in the sun's outer layers absorbs that wavelength, the so-called $H\alpha$ line. Hydrogen is present in the lightning channel due to the high-temperature break-up of water vapor (H_2O). Since hydrogen in the lightning channel radiates at 6563 Å ($H\alpha$) (see Chapter 11), it follows that an $H\alpha$ filter that passes only light near this wavelength both allows the channel to be photographed and prevents rapid film fogging by daylight. For maximum effectiveness, the film used should have good red sensitivity. Kodak Linagraph Shellburst is perhaps the best for the purpose. In cloudy weather at f/11, a daytime exposure of several minutes should be possible without excessive film fogging. A 2x2 in. $H\alpha$ filter with a bandwidth of about 40 Å costs about $200. (2) Triggering the camera shutter can be accomplished with instruments that respond to the electrical signals generated in the cloud or by the stepped leader prior to the first return stroke (Refs. 10.11, 10.12). In this way the first stroke can be photographed. Essentially, the shutter is tripped by a solenoid coupled to a radio antenna and appropriate electronics.

---

*One Å (Ångstrom) equals one ten-billionth of a centimeter. There are 2.54 centimeters to the inch.

chapter eleven

How Hot Is Lightning?

The lightning return stroke is more than four times hotter than the surface of the sun. The peak temperature of lightning is greater than 50,000°F. The surface of the sun has a temperature of about 11,000°F.

Exactly how hot the lightning return stroke channel gets is not known. The best peak temperature measurements made to date represent the average temperature existing during a time interval of a few millionths of a second. For time varying systems, average values are necessarily less than peak values. For example, the lightning temperature could be very high for a few billionths of a second and relatively low for the remainder of the millionths-of-a-second measuring time interval. The resultant average temperature would then be close to the low value. Lightning temperature has been determined by examining the characteristics of the light emitted by the channel.

The lightning channel is composed of very hot air. Air at room temperature is made up primarily of nitrogen and oxygen molecules. A nitrogen molecule consists of two joined nitrogen atoms; an oxygen molecule of two joined oxygen atoms. The nitrogen atom has a core or nucleus containing seven positively-charged particles (protons) and seven uncharged particles (neutrons). Orbiting the nucleus at relatively large radii are seven negatively-charged electrons. (The electrons circle the nucleus much as the earth and other planets circle the sun.) The oxygen atom consists of eight protons, eight neutrons, and eight electrons. As the temperature of air at atmospheric pressure is increased above room temperature to about 12,000°F, the heat causes the molecules to break apart into atoms. With a further increase in temperature to about 30,000°F each atom loses one of its electrons, and with higher temperatures still (say above 60,000°F), more electrons are lost. An atom which has lost an electron or electrons is called an *ion*. If one electron is lost, the atom is said to be singly ionized; if two, doubly ionized, and so on. The lightning channel is composed primarily of nitrogen atoms and ions, oxygen atoms and ions, and free electrons. How do we know this?

If sunlight is passed through a prism, the light is decomposed into its component colors or spectrum. (The rainbow is the sun's spectrum produced by water droplets.) Sunlight is composed of a range of colors varying in hue continuously from red to orange to yellow to green to blue to violet. Incandescent solids (e.g., tungsten filaments) or incandescent gases at very high pressure or occupying large volumes (e.g., the sun) produce continuous spectra; that is, light which includes all colors. Luminous gases at lower pressure or occupying small volumes (e.g., the lightning channel) produce spectra with "lines" at characteristic wavelengths. A given molecule, atom, or ion is capable of emitting radiation only at specific wavelengths which are different for different kinds of particles. Each molecule, atom, or ion has its own unique radiation "signature" by which it can be positively identified. For example, in the visible wavelength region a nitrogen atom radiates primarily one red spectral line while a nitrogen ion radiates primarily a number of blue lines. We can get a rough idea of the temperature of air by determining from the radiation emitted by the air whether it is predominantly composed of molecules, atoms, or ions. A more exact determination can be made by examining the intensities of the characteristic spectral lines from a given molecule, atom, or ion.

A spectrometer is an instrument that disperses the light from a source so that characteristics of the component spectrum can be measured. The dispersion is effected by either a prism or a diffraction grating. A drawing of a lightning spectrometer is shown in Fig. 11.1. Light from the lightning channel passes through the transmission diffraction grating and is split into its spectral components. These components as well as an undiffracted image of the lightning channel are focused by a lens onto the channel isolator slit assembly. For illustrative purposes, the lightning in Fig. 11.1 is assumed to contain only three spectral lines: a red, a green, and a blue. Note that each of the spectral lines has the shape of the lightning channel from which it came. If a stationary piece of photographic film were put in front of the channel isolator slit assembly, a photograph like that in Fig. 11.2 would be obtained. The photograph shown was taken by placing an inexpensive transmission grating† over the lens of a 35 mm camera while taking a time exposure (see Chapter 10) until lightning occurred. In Fig. 11.2, the red line to the far left (the H_α line discussed in the previous chapter) is emitted by hydrogen atoms present in the channel due to the break-up of water vapor (H_2O). Some water vapor is always present in the air; quite a lot may be present during a thunderstorm. The red line just to the right of the hydrogen line is emitted by nitrogen atoms. Most of the remaining lines are emitted by singly ionized nitrogen atoms.

---

†A page-size sheet of diffraction grating can be purchased for a few dollars. One supplier is Edmund Scientific Co., Barrington, N.J.

Spectra such as that in Fig. 11.2 yield no information about what is happening in the lightning channel as a function of time, since all the light of a given wavelength is recorded at the same place on the film no matter when it is emitted by the channel. With the help of Fig. 11.1 we see how to obtain time-resolved lightning spectra. The channel isolator slit allows the spectrum emitted by a short section of the lightning channel to fall on a piece of moving film at the back of the slit. Thus the spectrum is streaked out in time on the moving film. In the example shown, the green line appears at the earliest time followed by the blue and then the red lines. A time-resolved spectrum of a long spark in air is shown in Fig. 11.3 (Ref. 11.1). All existing time-resolved lightning spectra have been taken on black and white film since it permits much easier intensity measurements. Obtaining lightning spectra is too difficult a job to waste a spectrum by taking it on color film. The spark and lightning spectra differ primarily in that the lightning spectrum is stretched out three to five times longer than the spark spectrum (Ref. 11.1). For example, a nitrogen ion spectral line might last 5 millionths of a second in the spark, whereas for a typical lightning stroke it might last 20 millionths of a second.

From measurements of the intensities of the various spectral lines and use of appropriate theory, channel temperature can be determined as a function of time (Refs. 11.2, 11.3). A graph of typical lightning return stroke temperature vs. time is shown in Fig. 11.4. The peak temperature measured is about 55,000°F. The actual peak temperature could be higher as was previously noted. The temperature falls to about half of peak value in about 30 millionths of a

Fig. 11.1. A lightning spectrometer. Lightning image is broken up into its spectrum by transmission grating (similar to prism). Lens focuses various spectral images of lightning, as well as a "white light" image, on the channel isolator slit assembly. A spectrum from one section of the channel passes through the slit and is recorded on the moving film.

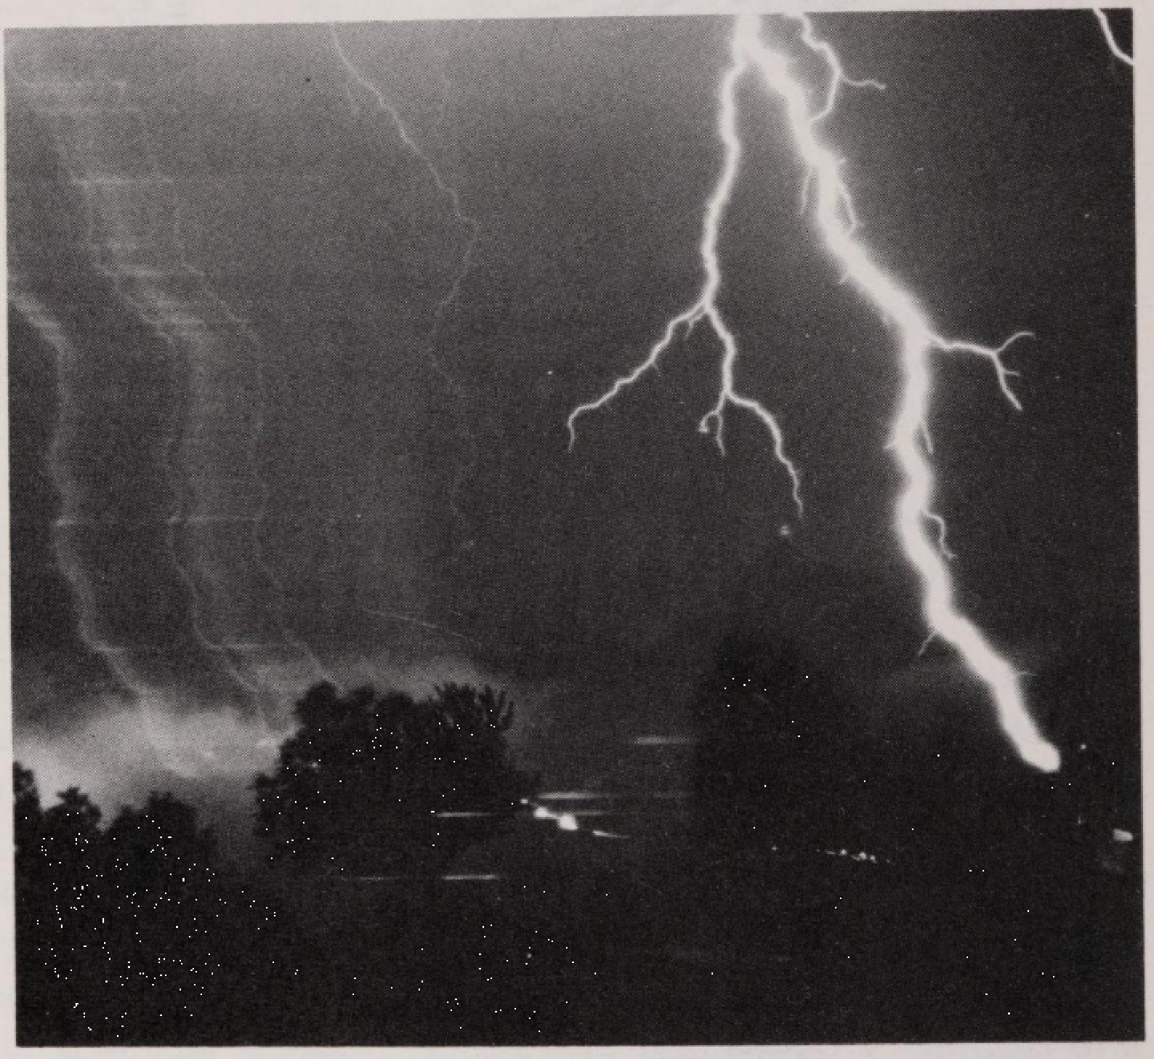

Fig. 11.2. Lightning spectrum as might be obtained by putting stationary photographic film in front of the channel isolator slit assembly of Fig. 11.1. Actually, the photograph was taken by placing an inexpensive diffraction grating in front of the lens of a 35 mm camera. (Courtesy, Richard E. Orville, State University of New York at Albany) (Reproduced in color on inside front cover)

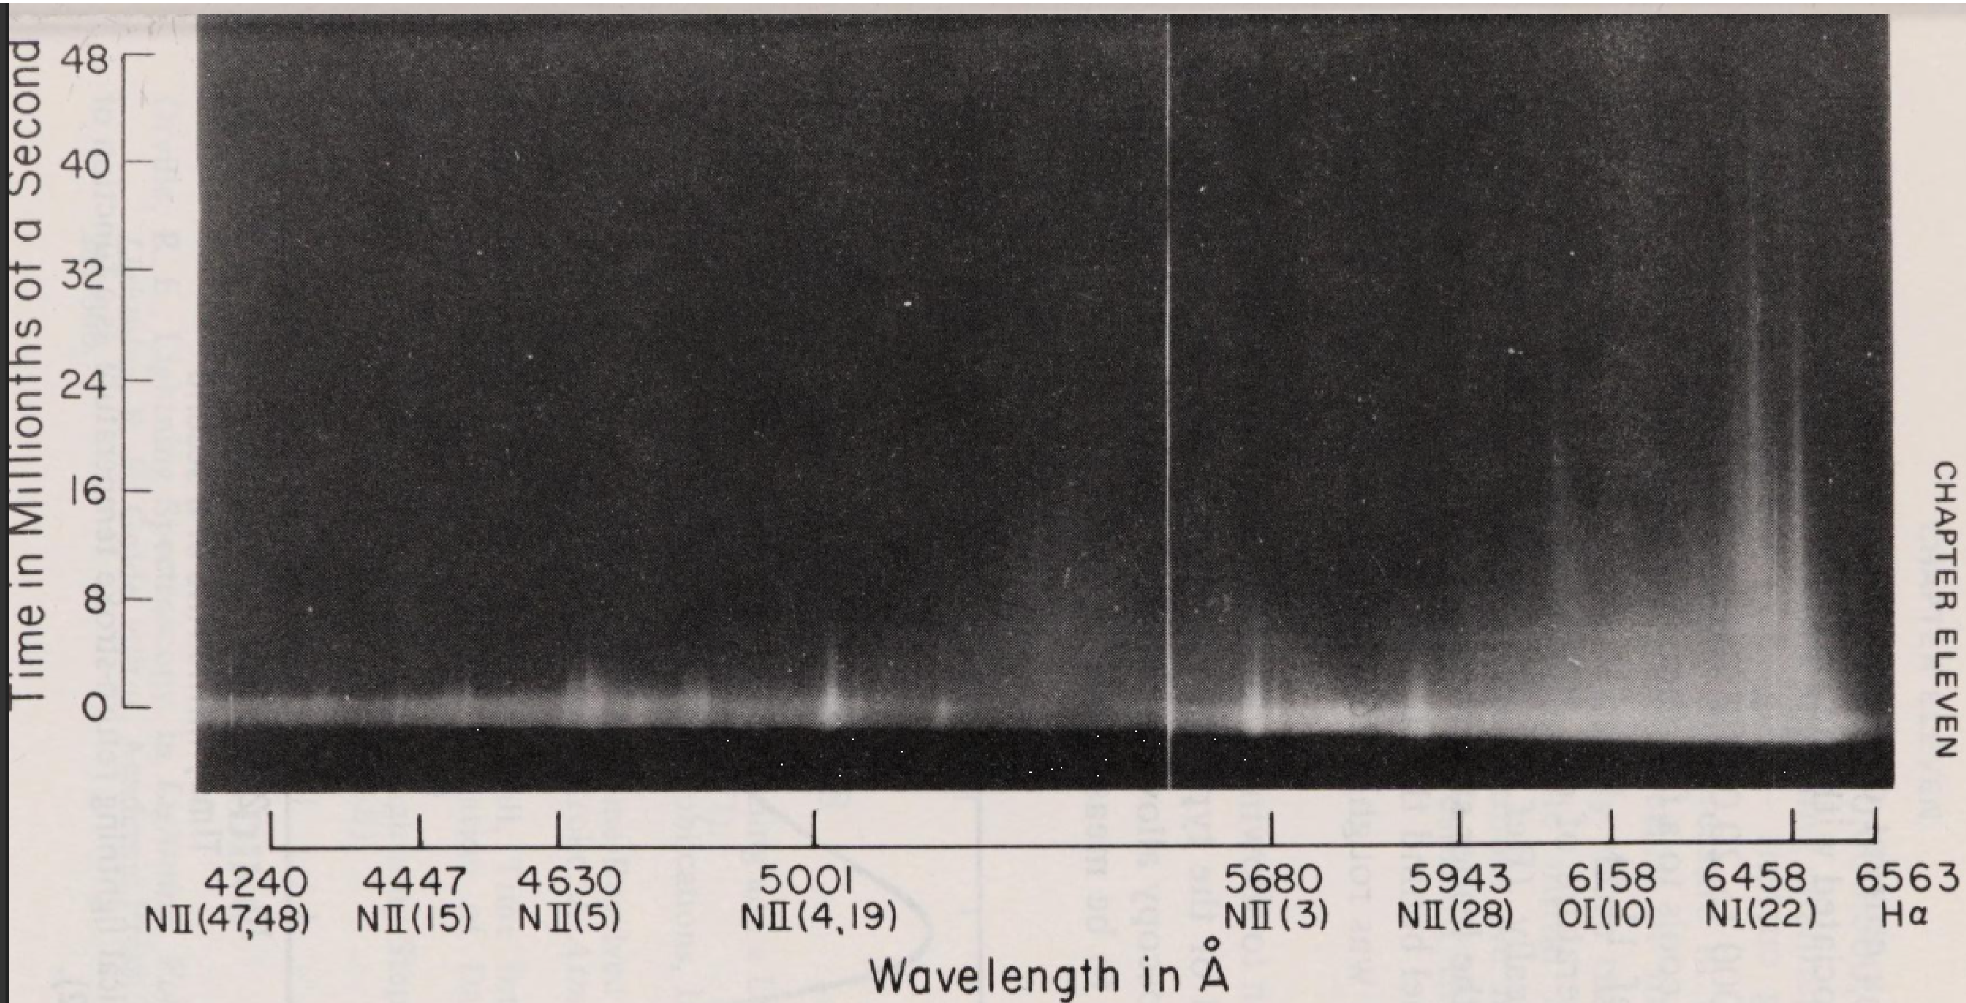

g. 11.3. Time-resolved spectrum of a 15 ft laboratory spark (Ref. 11.1) as obtained on the moving film of a ectrometer similar to that shown in Fig. 11.1. NI is neutral nitrogen, OI neutral oxygen, NII singly ionized nitrogen. ne numbers in parenthesis following the species designation are the multiplet numbers found in the technical erature. One Å (Ångstrom) equals one ten-billionth of a centimeter. There are 2.54 centimeters to the inch. Zero time ıs been arbitrarily set at the point where blue radiation first appears. (Reproduced in color on the inside back cover) second. For a current of about 100 amperes in the lightning channel (associated with the return stroke current tail or with a continuing current – Fig. 5.7) the temperature will be roughly 15,000 to 20,000°F. When the stroke current stops, the channel cools to a few thousand degrees in hundredths of a second (Ref. 11.4).

The temperature of one stepped-leader has been measured spectroscopically (Ref. 11.5). The peak temperature associated with the leader step was about 50,000°F. Temperature in the channel behind the step decreased with distance up the channel and was roughly 25,000°F five step lengths beyond the step.

In addition to allowing a determination of the channel temperature and of the types of particles in the channel, quantitative spectroscopy allows the number densities of all the channel particles to be measured. For example, it has been determined that there are over 1,000,000,000,000,000,000 free electrons per cubic inch in the lightning channel (Refs. 11.2, 11.3).

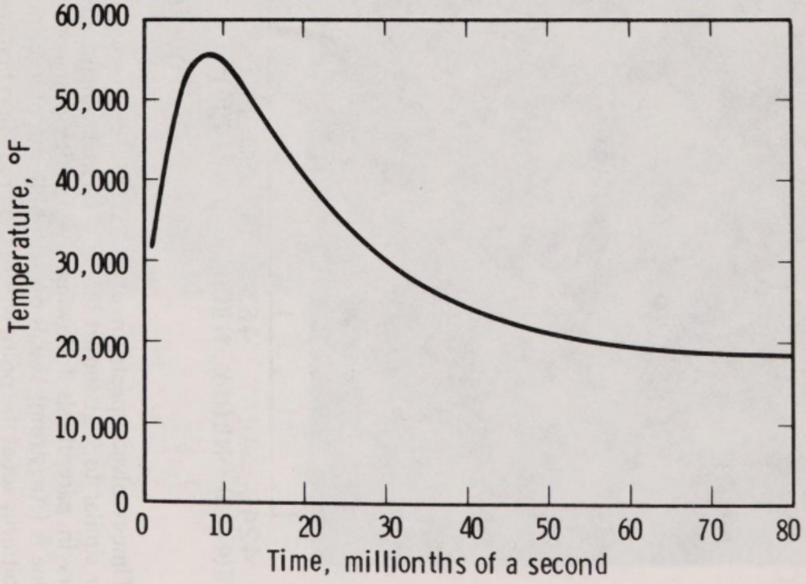

Fig. 11.4. Typical lightning return-stroke temperature as a function of time. (Ref. 11.2).

Also, spectroscopy permits the pressure in the lightning channel to be determined as a function of time. It is the initial high channel pressure (possibly more than 100 times atmospheric pressure) caused by the initial high channel temperature which produces the thunder we hear. We will consider channel pressure and the resultant thunder generation in the next chapter.

chapter twelve

How Is Thunder Generated?

How Can It Be Used To Measure The Distance And Length Of The Lightning Channel?

Throughout recorded history there has been a succession of interesting views on the origin of thunder. Aristotle, in the fourth century B.C., believed that thunder was the noise created when "dry exhalation" forcibly ejected from a cooling cloud struck the surrounding clouds – "dry exhalation", according to Aristotle, being one of the constituents of air (Ref. 12.1). We know now that there is no such substance. Interestingly, Aristotle thought that the origin of thunder preceded that of lightning and that the latter was a "burning wind" produced after the impact of the "dry exhalation" on a surrounding cloud. Lucretius, in the first century B.C., wrote that thunder was produced by clouds banging together (Ref. 12.2). In 1637 Descartes, the mathematician after whom the cartesian coordinate system is named, suggested that thunder was an organ-pipe effect: that thunder was due to a resonance of the air between two clouds occurring when a higher cloud descended upon a lower cloud (Ref. 12.3).

All of these early theories erroneously associated thunder with clouds rather than with the lightning channel. Later speculation regarding the origin of thunder generally associated thunder with the lightning channel. For example, Benjamin Franklin wrote in 1749 (see Chapter 1) that lightning and laboratory sparks were similar in that they both gave a "crack or noise in exploding". The correct meaning for Franklin's "exploding" was not generally agreed upon until the twentieth century. In the mid-nineteenth century the accepted theory seems to have been that lightning produced a vacuum along its path, and thunder resulted from the subsequent motion of air into the vacuum. Two other theories that achieved some respectability involved (1) the chemical explosion of gaseous materials created by the lightning, and (2) the creation of steam explosions along the heated lightning path. One of the first adequate descriptions of the origin of thunder was published by M. Hirn in 1888 (Ref. 12.4).

The thunder we hear is, in fact, created in the following way: The return stroke rapidly deposits a large amount of energy along the leader channel. That channel is heated by the energy input to above 50,000° F (see Chapter 11). Heating of a short section (say 10 yards) of channel takes only millionths of a second and hence the channel section has no time to expand while it is being heated. Air heated from room temperature or from a leader temperature of a few thousand degrees to above 50,000° F without having time to expand attains a pressure considerably in excess of normal atmospheric pressure (1 atmosphere). The initial pressure of the return stroke channel is definitely in excess of 10 atmospheres and may be 100 atmospheres or more. The high pressure channel rapidly expands into the surrounding air (initially at atmospheric pressure) and compresses it. This disturbance of the air propagates outward in all directions. For the first ten yards or so it propagates as a *shock wave* (a major disturbance in the air which travels faster than the speed of sound) and after that as an ordinary sound wave (small compressions and expansions of the air density). The sound pulse from a short section of lightning channel lasts less than 0.1 seconds and travels at about 1090 ft/second (about 0.21 miles/second) at sea level. The thunder we hear, then, is the pressure variations induced in the air by the expansion of each part of the lightning channel (main channel and branches) due to its initial high pressure.

Since sound travels about a foot in a thousandth of a second and the return stroke heats the entire lightning channel in less than a thousandth of a second (see Chapter 9), for all practical purposes each point on the lightning channel can be considered to emit a pulse of sound (or a shock wave) at the same time. Because light emitted by the return stroke channel travels away from the channel at 186,000 miles/second (or a mile in about 5 millionths of a second), we see light almost simultaneously with channel formation, but the sound of the thunder from that channel frequently takes many seconds to reach us. The initial thunder heard comes from the point on the lightning channel nearest to the observer. The last sound (excluding echoes) comes from the point farthest away. In Fig. 12.1, a 2-mile long intracloud discharge is oriented along the line of sight. We assume (direct evidence is lacking) that sound generation by the intracloud discharge occurs essentially simultaneously at all points on the channel as it does with the ground discharge. From the time it takes for the first sound to arrive, we can establish the distance to the nearest point on the channel. The first sound, traveling about 0.21 miles/second, arrives from the nearest channel point in about 13.5 seconds; multiplying these two figures provides the distance to the

nearest point on the channel – 2.8 miles. (In other words, if the time until the thunder arrives is T, the distance to the channel section producing the thunder is roughly T/5, the formula given in Chapter 10.) Sound from the far end of the channel, 4.8 miles away, arrives about 23 seconds after the channel is created, ending the thunder. The duration of the thunder is about 9.5 seconds, from which we can establish the channel length (channel length in miles = 9.5 seconds x 0.21 miles/second). The result represents the actual channel length only if the channel is oriented along the observer's line of sight. Otherwise it is an underestimate of the true length (that is, the true length is longer than the calculated value) as we can see by reference to Fig. 12.1 and 12.2.

In Fig. 12.2, a 2-mile long channel to ground produces sound from its base which arrives at the observer 2 miles from the base in about 9.5 seconds (2 miles = 9.5 seconds x 0.21 miles/second). Sound from the top of the channel, 2.8 miles away, arrives in about 13.5 seconds and thus the total thunder duration is about 4.0 seconds. By measuring only the thunder duration we can conclude that the minimum channel length that could have produced the thunder was 4.0 seconds x 0.21 miles/second = 0.84 miles. The true channel length, 2 miles, is of course longer than the calculated minimum value. Sometimes actual thunder durations are as long as a minute (minimum channel lengths of over 10 miles).

To summarize, from a measurement of the time of arrival of the first sound of thunder we can determine the distance to the closest point of the lightning channel; and from the thunder's duration we can determine a minimum length for the channel. In both cases a distance is derived by multiplying the appropriate time interval by the speed of sound. This is the case even if the channel under consideration is not straight, as the reader may easily prove to himself. It is worth noting that a visible channel to ground may be much farther away than its thunder would indicate if the in-cloud part of the lightning channel passes overhead.

Time, in seconds, From Creation
of Return Stroke Channel

Fig. 12.2. Cloud-to-ground lightning flash and its thunder.

Thunder is generated by each of the return strokes in a multiple-stroke flash. Since the time between the first and last strokes may be a few tenths of a second, the thunder duration may be increased by a few tenths of a second over the time taken for sound to arrive from different ends of the channel. The error made in computing minimum channel lengths due to this effect is not important. It should be noted that the last stroke in a multiple-stroke discharge usually has the greatest length (see Chapter 10), and hence produces the longest lasting thunder. It is therefore the length of the final stroke that is measured.

In addition to thunder produced by return strokes, sound is also produced by stepped leaders and dart leaders. Leader thunder is relatively weak compared with that produced by return strokes.

Why does thunder sound like it does? Why does it rumble, roll, peal, and clap? Two factors must be considered: the intensity or loudness of the sound, and its pitch or frequency. We look first at the loudness. If a section of the tortuous lightning channel is perpendicular to the observer's line of sight, all points on that section will produce sound that arrives almost simultaneously at the observer, and the result is a high-intensity sound – a peal or a clap. If a channel section is along the observer's line of sight (as with the whole channel in Fig. 12.1), the sound arrival times from various points on the channel will be spread out, resulting in a low-intensity sound – a rumble or a roll. Channel tortuosity enhances the rumbling effect. Typical thunder consists of rumble and roll on which three or four peals or claps are superimposed.

Now to pitch. As we have seen, thunder generation is similar to an explosion. As everyone knows, small explosions (e.g., small firecrackers) make a high pitched sound while large explosions (e.g., large aerial fireworks or sticks of dynamite) make a low pitched sound. The larger the energy input, the lower the pitch. Thunder generally has a pitch, or frequency, of about 50 cycles per second. From measurements of thunder pitch and use of appropriate theory, scientists have determined the energy input per unit length of lightning stroke channel (100,000 to 1,000,000 watt-seconds per yard of channel length). Thunder pitch is influenced by two additional factors: First, the lower the air density for a given energy input to the lightning channel, the lower the thunder pitch; this means that thunder from a channel at high altitude should have a lower pitch than thunder from a channel near ground. Second, air filters out the higher pitches preferentially, so that the further away thunder is heard from its channel, the lower should be its pitch.

Thunder is seldom heard more than 15 miles away from a lightning channel. The reason is that, due to the effects of temperature and wind variation with height, sound waves generally curve upward in the air under and surrounding thunderstorms. Thus, the thunder from a lightning channel passes over the head of an observer if he is more than about 15 miles from the channel. If he climbed a tall enough ladder, he would hear the thunder.

Within a few hundred yards of a lightning strike, the observer hears one loud (terrifying) bang possibly preceded by hissing or clicking or something similar to cloth tearing. The bang is the sound wave from the channel base. No long-duration thunder is usually heard because, due to the upward curvature of the sound waves, the thunder from sections of the channel above the channel base pass over the observer's head. The various sounds reported to occur before the loud bang may be due to the downward-moving stepped leader, to upward-moving discharges attempting to meet the stepped leader, and/or to a general corona-discharge blanket at the ground.

chapter thirteen

Does Lightning Occur Without Thunder? Thunder Without Lightning?

What Is Heat Lightning? Sheet Lightning?

Ask a lot of people the question "Did you have lightning in your vicinity yesterday?" and, assuming there was lightning, at least one person will invariably answer "No lightning, but a lot of thunder!" Possibly, this is just another way of saying that thunder was heard but lightning wasn't seen. More likely, the answer indicates that the person does not understand the relation between lightning and thunder.

We have seen in the previous chapter that the origin of thunder is the explosive expansion of the lightning channel following a rapid energy input to the channel. Since it is the lightning channel that creates the thunder, there can be no thunder without lightning. But can there be lightning without thunder? Strictly speaking, no. Every electrical discharge, when initiated, produces some noise. However, if we ask whether there is lightning whose thunder may be inaudible a relatively short distance from the channel, the answer is apparently yes. There have been lightning flashes reported to strike the Washington Monument without producing audible thunder, and flashes to the Empire State Building which were reported to have produced a sound described as being the same as if a paper bag full of water had been dropped a short distance to the floor (Ref. 13.1).

As noted in Chapter 6, lightning flashes to tall buildings are generally initiated by stepped leaders which move upward from the building tops. The current in a structure-initiated flash rises slowly to a peak current of a few hundred amperes and this low level of current typically flows for a few tenths of a second. Often this continuous current is punctuated by current peaks caused by return strokes whose leaders are initiated in the cloud and travel from cloud to building top down the active channel. Sometimes no return strokes occur and the flash consists of only the low-level current. It is the upward-initiated discharge with no return strokes that might be expected to generate very little sound. Its current is small and increases slowly compared to the current of a typical return stroke; the energy input is neither large nor rapid and thus cannot lead to the explosive channel expansion and typical thunder characteristic of the usual return stroke channel.

What about "heat lightning"? Why does it have no thunder? Before we answer this question, we had better define what we mean by "heat lightning". In common terminology, heat lightning is the name given to the illumination of distant clouds close to the horizon which occurs without thunder and in the absence of a visible lightning channel. Heat lightning apparently is so named because it occurs on hot nights. The fact that it occurs on hot, generally humid nights is due simply to the fact that hot humid air near the ground is an ingredient in the thunderstorm recipe (see Chapter 7). The nocturnal thunderstorms accused of generating heat lightning actually produce the usual intracloud and cloud-to-ground lightning flashes. The light from these flashes illuminates the clouds from within and by reflection so that the clouds are easily seen even when they are sufficiently far away (say 30 miles) that individual lightning channels cannot be discerned. Since thunder cannot generally be heard more than about 15 miles from a lightning channel (see Chapter 12), the distant heat lightning produces no audible thunder.

"Sheet lightning" is a close relative of heat lightning. Sheet lightning is the name given to the intracloud discharges which light up a large cloud area simultaneously, giving the impression of a sheet of light. Sheet lightning may or may not produce audible thunder, depending on its distance from the observer.

chapter fourteen

Do Gushes Of Rain Follow Thunder?

Observers of thunderstorms, from antiquity to the present, have noted that a heavy gush of rain often reaches ground a minute or two after a lightning flash and its accompanying thunder (Refs. 14.1, 14.2). Since precipitation is believed necessary to provide a thunderstorm with its electrical charge (see Chapter 8), it could be argued that a rain gush occurring in the cloud provides the charge separation that causes the lightning. On the other hand, it could just as well be argued that the lightning or its thunder modifies the character of the precipitation in the cloud in such a way as to cause a rain gush. Finally, it is also possible that both lightning and the rain gush are caused by some other effect or that it is only fortuitous that they appear to be related. Not until the 1960s did radar observations of the precipitation in clouds before and after lightning show that lightning and thunder precede the formation of the rain gush (Refs. 14.1, 14.2).

As long ago as 58 B.C., Lucretius wrote that gushes of rain were caused by thunder. Modern proponents of this currently unpopular view suggest that the compression and rarefaction waves associated with the thunder accelerate some drops relative to others causing collisions between the drops which would otherwise not have occurred. The collisions allow small drops to coalesce into bigger drops which are heavy enough to fall out of the cloud as rain. It is interesting to note that from radar measurements of clouds there is evidence to suggest that thunder can cause supercooled water droplets (water droplets below 32°F which are not frozen) in the clouds to turn to ice (Ref. 14.3). Further, supercooled water droplets can be turned to ice crystals in the laboratory by the sound from a toy pop gun or by a bursting balloon (Ref. 14.4). The freezing mechanism involved in both the laboratory and the cloud may be the lowering of the droplet temperature by the expansion of the air associated with the sound wave rarefaction.

Most investigators now believe that the lightning/rain gush relation is electrical rather than acoustic. As seen in Chapters 8 and 9, the top of the lightning channel is found in the N-region of the cloud. The N-charge resides on supercooled water and ice particles. Stepped and dart leaders are negatively charged, drawing their charge from the N-region. The return stroke drains the negative charge on the leader to the ground. After the return stroke has reached the top of the lightning channel, the whole channel, a good conductor tied to ground, becomes positively charged in response to the negative cloud charge above and around it. The leader-return stroke process results in a negatively-charged leader channel being replaced by a positively-charged channel in a time that is short compared to that in which any of the surrounding negative cloud charge can move appreciably (Fig. 9.3a). If electrical effects cause the rain gush, the charged cloud particles must coalesce in response to the rapid change in the sign of the charge on the lightning channel.

The mechanism for coalescence most closely examined is that proposed by Bernard Vonnegut and Charles Moore (Refs. 14.1, 14.2, 14.5). They postulate that the cloud droplets in the immediate vicinity of the newly-completed return stroke channel acquire a net positive charge from the positively-charged channel. Since similar charges repel one another, the positively charged droplets fly away from the channel, initially at perhaps tens of yards per second, colliding and coalescing with the surrounding negatively-charged droplets. The initially-stationary negative droplets are attracted toward the moving positive droplets by virtue of their opposite charge, further increasing the collision rate. The positive droplets may travel about 10 yards, increasing in size all the time. The end result is a group of large water drops surrounding the channel.

If the process just described is to produce a rain gush, it must be operative over a reasonably large volume of the cloud. Vonnegut and Moore suggest that this is the case because the lightning channel in the cloud has a tree-like structure. A drawing of this structure is shown in Fig. 9.3. Some idea of the extent of the structure may be inferred from electrical discharges in insulating materials (the cloud is essentially an insulator). In Fig. 14.1 a photograph of a plastic block in which a tree-like discharge has taken place is shown. The block was charged negatively by shooting high energy electrons into it. The tree-like discharge occurred when a grounded electrode was placed at the edge of the block. Unfortunately, there is at present no direct evidence regarding the extent of the lightning channel structure in the cloud, and we must await future lightning research to determine its actual structure.

Some of the gushes of precipitation that fall after lightning are in the form of hail (Ref. 14.2). When a rain gush forms by a coalescence process at temperatures below 32°F, the drops may freeze as they become large and then continue their growth as hail particles.

While most rain gushes are preceded by lightning, it does not follow that lightning invariably produces rain gushes. Whether there is a rain gush or not depends, among other things, on the liquid water content of the cloud. If this is too low, heavy rain cannot form.

Although it is possible for lightning to occur in the absence of appreciable precipitation, the two usually go hand in hand. Recently the amount of rainfall reaching the ground near Tucson, Arizona has been correlated with the number of cloud-to-ground discharges (Ref. 14.6). These results and those of earlier studies show that the greater the number of lightning discharges, the greater the rainfall. (The clouds which produce both the most rain and the most lightning are those of the greatest vertical extent.) From measurements of the amount of rainfall and the number of lightning flashes occurring near Tucson between 1 and 6 p.m. on 52 days, it was determined that an average of about a thousandth of an inch of rain arrives at the ground for each cloud-to-ground lightning stroke observed. On 23 days of heavy rain (exceeding 0.10 in.) there was an average of 175 cloud-to-ground lightning flashes per day. On 29 days of light rain (less than 0.01 in.) there was an average of only three flashes per day.

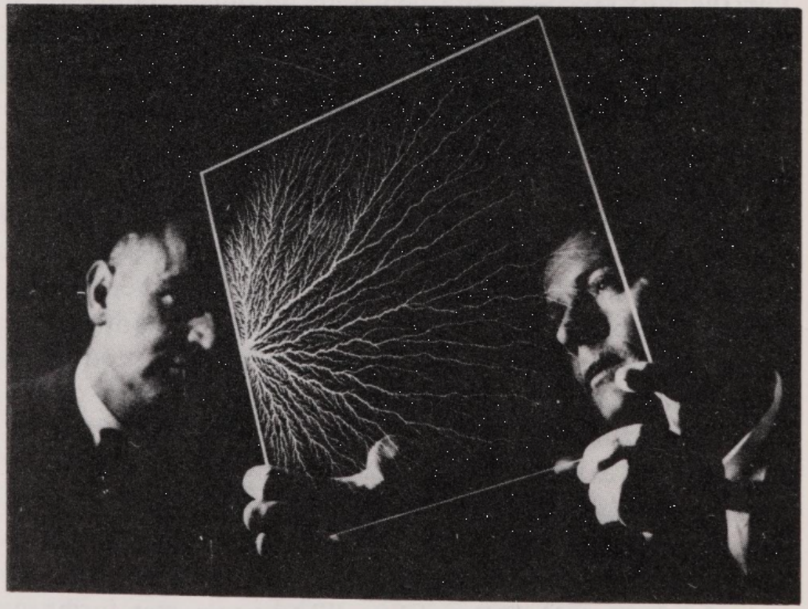

Fig. 14.1. Electrical breakdown in a plastic block. The tree-like structure which extends into the block may be similar to the lightning discharge structure extending from the top of the channel upward into the cloud. (Courtesy, Arthur D. Little, Inc.)

chapter fifteen

What is Ball Lightning?

Are UFOs and Ball Lightning Related?

Ball lightning (in French, *boules de feu* or *foudre sphérique;* in German, *Kugelblitz*) is the name given to the mobile luminous spheres which have been observed during thunderstorms. A typical ball lightning is about the size of an orange or a grapefruit and has a lifetime of a few seconds. A 19th century woodcut depicting the occurrence of a somewhat larger than average ball lightning is shown in Fig. 15.1. A number of compilations of eye-witness reports of ball lightning have been published (Refs. 15.1 to 15.6). Visual sightings are often accompanied by permanent material damage, sounds, and odors. Nevertheless several noted scientists have attributed ball lightning to persistence of vision (after seeing a bright lightning channel) or to other optical effects (Ref. 15.7).

In a letter to the editor of the London *Daily Mail* (Ref. 15.8) W. Morris described an unusual incident in which a ball lightning caused a tub of water to boil:

> ● During a thunderstorm I saw a large, red hot ball come down from the sky. It struck our house, cut the telephone wire, burnt the window frame, and then buried itself in a tub of water which was underneath.
>
> The water boiled for some minutes afterwards, but when it was cool enough for me to search I could find nothing in it.

As a researcher in the field of lightning, the writer has personally received over one hundred unsolicited eye-witness accounts of ball lightning. Here are five representative observations:

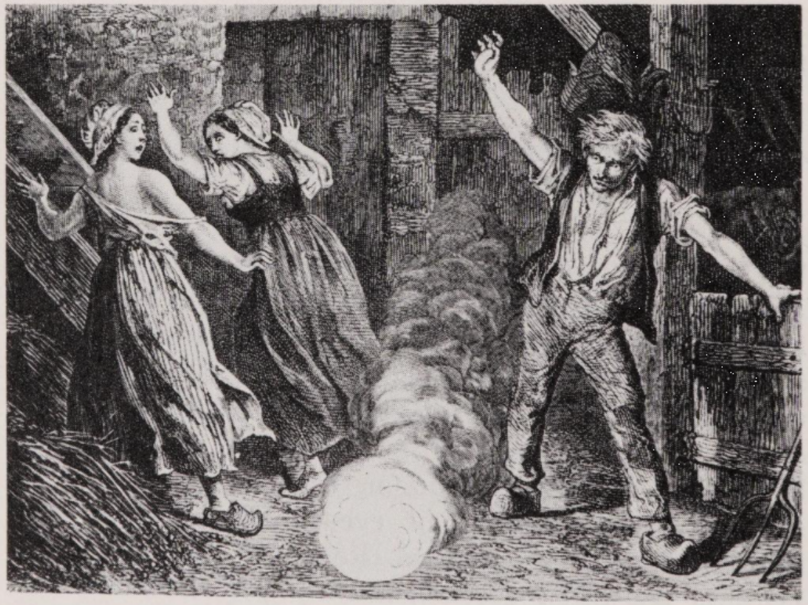

Fig. 15.1. Ball lightning in a 19th century woodcut. The original title, translated from French, reads "Ball lightning crossing a kitchen and a barn." Perhaps the ball lightning came down the chimney used to exhaust the cooking fires. How the young lady's blouse came to be in such a state of disarray is not known. (Courtesy, Burndy Library)

● I was visiting my uncle's farm in Eastern Norway where the country is very flat and the summers warm with cloud gatherings and thunderstorms in the middle of the day. One day when my cousin and I went shopping, a thunderstorm worse than usual broke out. The rain poured down, and we stayed in the open door of the shop, looking out. Suddenly we saw a glowing ball, the size of a small football [soccerball], passing the door at great speed a little above ground level. We had never heard about 'ball lightning' before, and wondered what it might be. When the rain stopped, we started on our way home and walked along a path leading through the forest. Then it started thundering again, and another ball, just like the first one, came rolling towards us. Now we got curious, but not very much – to 10-year-old children there are so many strange things to wonder about – so what is a rolling glowing ball more or less? Then my uncle came to meet us, because he thought we might be frightened by the heavy thundering, and the first thing he said was, 'Did you see the ball lightning?' Not till then did we realize that we had seen something strange and dangerous.

● While outdoors during a particularly violent thunderstorm such as are common there [Iowa], I heard a heavy rushing noise like an extra strong wind. This caused me to look about me and I saw a ball of fire, yellowish white about the size of a wash tub bouncing down the dirt road. The ball traveled a little faster than one could run. I did not see from where it came. I watched the ball travel about a city block, when it struck a small shed, maybe 10 feet by 12 feet in which a horse was stabled. The shed seemed to explode and the horse was killed.

● Near Murray's dairy, a property on the Queanbeyan road on the then outskirts of Canberra [Australia], and not far from what is now the industrial area of Fyshwick, I was riding along the right hand side of the road, just off the paving to prevent a possible slip and fall on the wet surface, and about 20 to 25 yards ahead, on the left hand side and also off the bitumen, a farm employee was leading a Shorthorn bull. There was very little, if any rain at that time. I can clearly recall that there was one of those periods of "quietness" that sometimes precedes a downpour. Just as I drew level with the bull there was one very loud bang or explosion and immediately down the white traffic line in the centre of the road appeared the fireball. It seemed to be about 6″ or 8″ off the ground, was about the size of a basketball like very golden butter in color, and had the appearance of being "spun" or "fuzzy", like silk threads or wool, as distinct from a "molten" liquid look. It did not sparkle – just a ball of fuzz. It came straight down say three of the white marker lines. These have about equal distance of unmarked road between them, so I should say it travelled about 18 to 20 feet. Then it simply disappeared. It did not break apart. There was no further noise like an explosion. It was there one moment and not there the next.

The whole thing would have been over in probably two or three seconds, before the horse had time to be startled.

The young men leading the bull cried out – in Pure Australian – "What the bloody hell was THAT?".

As there was another downpour shortly, we did not stop to discuss it.

- I was standing in the kitchen of my home in Omaha, Nebraska while a terrible thunderstorm was in progress. A sharp cracking noise caused me to look toward a window screen to my left. Then I saw a round, iridescent (mostly blue) object, baseball size, coming toward me. It curved over my head and went through the isinglass [mica] door of the kitchen range, striking the back of the oven and spattering into brilliant streamers. There was no sound and no effect on me except a tingle as it passed over my hair. Later examination showed a tiny hole with scorched edges in the screen and isinglass, and scorch-like marks on the back of the oven.

- The whole family was sitting at the supper table when a ball about 4 inches in diameter came and fluttered about the center of the table. It made a buzzing noise and was about 8 to 10 inches above the dishes. Its color was a mixture of blue and orange and may have had some red. It fluttered about 5 to 6 seconds. I could easily have grabbed it had I dared to do so. Then it exploded with a loud bang like a large fire cracker and gave off a smell somewhat like city cooking gas which lasted several minutes. After it exploded the table was left as before, no dishes broken or moved about.

A number of photographs purported to be of ball lightning have been published (Refs. 15.9 to 15.14). Most of them are time exposures in which the ball lightning appears as a meandering ribbon of light. Some of the photographs may well be of automobile or other moving lights, or of stationary lights photographed by a moving camera. It appears that no motion pictures of ball lightning have been taken.

A phenomenon very similar to, if not identical with, ball lightning has been reported to occur in submarines due to the discharge of a high current (about 150,000 amp D.C. from a 260 volt source) across a circuit breaker (Ref. 15.15). In addition, the writer has received a number of reports of ball-lightning-like phenomena being initiated in electrical equipment, both with and without lightning present. One such thunderstorm-associated incident was reported by a retired professor and engineering department chairman at a major state university:

- In 1914 I was working for the Interurban Co. and happened to be in the main power house during a very severe thunder storm. We had recently installed a 600 volt dc rotary converter which supplied power to both the city and interurban lines. I was working on the main switch board and watching a bit carefully as there were many breakers opening. I looked up just in time to see a ball of fire about 15 to 18 inches in diameter come off the converter commutator and float at a good speed down the length of the switch board, maybe three feet above my head. Some hundred feet from the converter it struck the ceiling of an office room where a cat was asleep. The ball splashed in all directions like water and the cat sprang high in the air. The cat squalled loudly but seemed to be uninjured. In both cases there was the strong odor of ozone, but due to the constant lightning I would not attribute it to the 'ball lightning.'

Ball lightning has been seen by 5 to 10% of the population. Although it is generally thought that ball lightning is a rare phenomenon, recent research has shown that the numbers of ball lightning observers are not much different from the numbers who have observed lightning impact points (Ref. 15.6). The implication is that ball lightning is usually created at or near the lightning channel and that an appreciable fraction of all cloud-to-ground lightning flashes may give birth to ball lightning. Since the balls generally last for only a few seconds, they cannot get too far from the mother channel. Thus ball lightning may well be common, but rarely seen.

Ball lightning and St. Elmo's fire are sometimes confused. St. Elmo's fire is a corona discharge induced at a pointed conducting object by thunderstorm charges. Like ball lightning, St. Elmo's fire may assume a spherical shape. Unlike ball lightning, it must remain attached to a conductor, although it may exhibit some motion along the conductor. Further, St. Elmo's fire may last much longer than the typical ball lightning.

From the many published ball lightning observations, it is possible to compile a list of ball lightning characteristics:

Occurrence: Most observations of ball lightning are made during thunderstorm activity. Most, but not all, of thunderstorm-related ball lightning appears almost simultaneously with a cloud-to-ground lightning discharge. These balls appear within a few yards of the ground. Sometimes ball lightning is reported to appear near ground in the absence of a lightning discharge. Lightning balls have also been observed to hang in mid-air above the ground and have been observed falling from a cloud toward the ground.

Appearance: Ball lightning is generally spherical, although other shapes have been reported. Balls are usually 4 to 8 in. in diameter, with reported diameters ranging from 1/2 in. to many feet. Various colors have been observed, the most common being red, orange, and yellow. Luminosity is generally not exceptional but the balls can be seen clearly in daylight. They are usually reported to maintain a relatively constant brightness and size, although changes in brightness and size are not uncommon.

Lifespan: Ball lightning generally lasts less than 5 seconds. In a small fraction of the reports a lifespan of over a minute is indicated.

Motion: Lightning balls usually move horizontally at a velocity of a few yards per second. They may also remain motionless in mid-air or may descend from a cloud toward the ground. They do not often rise, as would be the case if they were spheres of hot air at atmospheric pressure subject only to gravity. Many reports describe balls which appear to spin or rotate as they move. Sometimes they are reported to bounce, typically off the ground.

Heat, sound, and odor: Rarely is the sensation of heat reported although there are accounts of lightning balls which burned barns and melted wires. One report (Ref. 15.5) describes a ball lightning which hit a pond of water with a sound "as if putting a red hot piece of iron into the water." Sometimes a hissing sound is said to be emitted. Many observers report an accompanying odor usually described as sharp and repugnant, resembling ozone, burning sulphur, or nitric oxide.

Attraction to objects and enclosures: Reports often describe balls attached to, and moving along, metallic objects such as wire fences or telephone lines. Some or all these observations may refer to a type of St. Elmo's fire. Lightning balls often enter houses through screens or chimneys, and sometimes through glass window panes. They are also reported to originate within buildings, on occasion from telephones. Balls can exist in an all-metal enclosure such as the interior of an airplane. For instance:

> • I was at the controls of a KC-97 USAF tanker aircraft, heavily loaded with JP-4 fuel for offload to B-47 bombers. En route to the refueling rendezvous (Elko, Nevada vicinity) we were in the clouds at 18,000′. There was light precipitation, temp. was above freezing and there was no turbulence.
>
> I recall that St. Elmo's fire was dancing around the edges of the aircraft front windows. (This is a not too uncommon occurrence but may have some significance to you.) The crew was experienced in all phases of all-weather operation and not concerned or apprehensive about any portion of the mission to be accomplished.

As I was concentrating on the panel (no outside visual references were visible) a ball of yellow-white color approximately 18″ in diameter emerged through the windshield center panels and passed at a rate about that of a fast run between my left seat and the co-pilot's right seat, down the cabin passageway past the Navigator and Engineer. I had been struck by lightning 2 times through the years in previous flights and recall waiting for the explosion of the ball of light! I was unable to turn around and watch the progress of the ball as it proceeded to the rear of the Aircraft, as I was expecting the explosion with a full load of JP-4 fuel aboard and concentrated on flying the aircraft. After approximately 3 seconds of amazingly quiet reaction by the 4 crew members in the flight compartment, the Boom operator sitting in the rear of the aircraft called on the interphone in an excited voice describing a ball of fire that came rolling through the aft cargo compartment abeam the wings, then danced out over the right wing and rolled off into the night and clouds! No noise accompanied the arrival or departure of the phenomenon. (Ref. 15.16)

- This communication records the observation of ball lightning in unusual circumstances. I was seated near the front of the passenger cabin of an all-metal airliner (Eastern Airlines Flight EA 539) on a late night flight from New York to Washington. The aircraft encountered an electrical storm during which it was enveloped in a sudden bright and loud electrical discharge (0005 h EST, March 19, 1963). Some seconds after this a glowing sphere a little more than 20 cm [8 inches] in diameter emerged from the pilot's cabin and passed down the aisle of the aircraft approximately 50 cm [20 inches] from me, maintaining the same height and course for the whole distance over which it could be observed.

. . . the relative velocity of the ball to that of the containing aircraft was 1.5 ± 0.5 meters [or yards] per second . . . the object did not seem to radiate heat. . . . the optical output could be assessed as 5 to 10 watts and its color was blue-white. . . . the course was straight down the whole central aisle of the aircraft. (Ref. 15.17)

Demise: Ball lightning decays in one of two modes, either explosively or silently. Explosive decay occurs rapidly and is

accompanied by a loud noise. Silent decay can take place either rapidly or slowly. Most lightning balls apparently exhibit a rapid decay. After the ball has decayed, it is sometimes reported that a mist or residue remains. Occasionally a ball lightning has been observed to break up into two or more smaller balls.

Types: There may be more than one type of ball lightning. For example, the ones that attach to conductors may differ from the free-floating balls; the balls that appear near ground level may differ from those that hang high in the air or those that fall out of a cloud.

Unfortunately, there is at present no adequate theory of ball lightning. For example, no theory can account simultaneously for the degree of mobility, the constancy of light output, and for the fact that the ball does not rise. Despite numerous theoretical models proposed, the causal mechanisms remain unknown. All theories fall into one of two general classes: those in which the energy source for the ball is postulated to be outside the ball (externally powered ball lightning) and those in which the sustaining energy is postulated to be stored within the ball itself (internally powered ball lightning).

In the internally powered models there are essentially six subclasses: (1) Ball lightning is gas or air behaving in an "unusual" way. It has been suggested that the ball lightning is slowly burning gas, is the light produced by the slow recombination of unspecified ions existing in the ball, is due to chemical reactions involving dust, soot, etc., and so on. (2) Ball lightning is a sphere of heated air or heated air containing various impurities at atmospheric pressure – Ref. 15.18. (3) Ball lightning is a very high-density plasma (ionized gas) which exhibits properties characteristic of solid materials – Ref. 15.19. (4) Ball lightning is due to one of several suggested configurations of closed-loop current flow contained by its own magnetic field. It has been shown that plasma containment of this type is not possible in air – Ref. 15.20. (5) Ball lightning is due to some sort of air vortex (like a smoke ring) providing containment for luminous gases. (6) Ball lightning is a high frequency electromagnetic field contained within a thin spherical sheet of ionized air – Ref. 15.21.

In the theories which provide the ball with an external power source, three types of power sources have been suggested: (1) A high-frequency (hundreds of megacycles per second) electromagnetic field, (2) a steady current flow from cloud to ground, and (3) focused cosmic-ray particles. (1) M. Cerrillo (Ref. 15.22) and P. Kapitza (Ref. 15.23) proposed that focused radio frequency energy from the thundercloud could create and maintain a ball lightning. Radio waves with the energy necessary to effect this mechanism have never been observed in thunderstorms. (2) D. Finkelstein and J. Rubinstein (Ref. 15.20), the writer and C. Helstrom (Ref. 15.24), and J. Powell and Finkelstein (Ref. 15.25) have suggested that a steady current flowing from cloud-to-ground would contract in cross section at the ball (originally provided by part of the lightning channel) and that the increased energy input due to the constriction of current could maintain the ball. This type of theory cannot account for the existence of ball lightning inside structures, particularly inside metal structures. (3) V. Arabadzhi (Ref. 15.26) has suggested that radioactive cosmic-ray particles could be focused by the charges of the thundercloud so that the cosmic rays would create an air discharge at one point in space. This would appear to be very unlikely.

Are UFOs (Unidentified Flying Objects) and ball lightning related? There are all kinds of UFOs. Some are hoaxes; some are misinterpretations of well-understood physical phenomena like meteors, not known to the observer or seen under unusual circumstances; some, like re-entry vehicles, are unpublicized objects of our advanced technology; some are

imperfectly understood physical phenomena; some may be due to poorly understood psychological effects; and, finally, some may be spaceships (true flying saucers). Although there are many observations of flying-saucer-like objects reported by reliable people (Refs. 15.27, 15.28), incontrovertible proof that interplanetary spaceships exist – a captured or crashed saucer – has not been forthcoming. The UFO literature referenced (Refs. 15.27, 15.28) and the references contained in that literature make fascinating reading.

But let us return to our original question. A small percentage of the UFO reports are so similar to a certain class of ball lightning reports that they both must refer to the same "imperfectly understood physical phenomena." These particular lightning balls are much larger, much brighter, and much longer-lived than the typical balls. They are reported to be 10 to 20 ft in diameter, give the impression of being as bright as lightning, and may last a minute or more. When such objects appear immediately after lightning, it is clear that they should be called ball lightning. Sometimes, however, they appear near or in clouds or in snow without the apparent presence of lightning, and occasionally such objects are reported in seemingly clear air.

chapter sixteen

What is Ribbon Lightning? Bead Lightning?

Ribbon lightning is the name given to the optical illusion occurring when a cloud-to-ground lightning flash is moved sideways an appreciable distance by the wind during the time between the component strokes of the flash. Each stroke in the flash is then seen separated horizontally in space. To the eye, each identically-shaped stroke (ribbon) appears to occur simultaneously. A photograph of ribbon lightning is shown in Fig. 16.1.

The first solid evidence that lightning flashes are generally composed of a number of separate strokes was provided in the 1880s by photographs of ribbon lightning. By the early twentieth century several investigators had obtained ribbon-like photographs of normal (not wind-blown) lightning by moving their cameras as the flash was occurring. Each component stroke of the flash appeared at a different

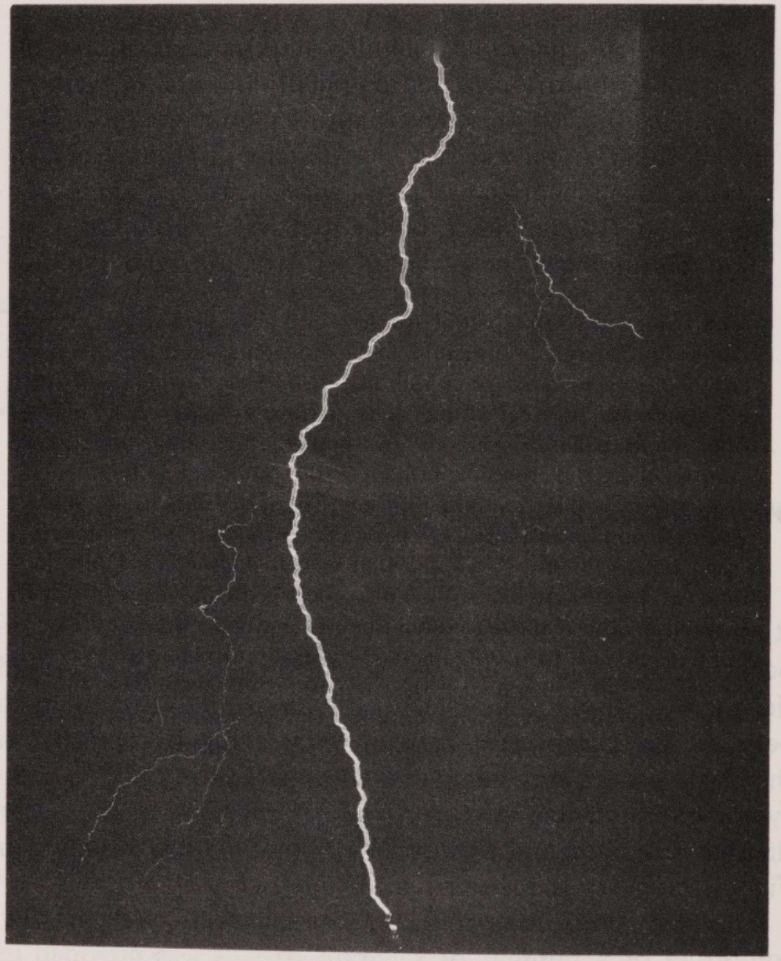

Fig. 16.1. Ribbon lightning near Tucson, Arizona photographed with a tripod-mounted camera. (Courtesy, George Marcek, Catalina High School, Tucson)

position on the film because the lens and film position had changed relative to the fixed lightning position during the time between strokes. The technique of moving (by hand or mechanically) a camera during a flash to time-resolve the features of the flash has yielded much valuable information about lightning. For example, in this way stepped and dart leaders were discovered and their velocities measured. Modern "streak" cameras which time-resolve various high-speed luminous events (including lightning) employ the same basic idea, relative motion between lens and film, as the hand-moved camera. The streak camera lens remains stationary while the motor-driven film moves at high speed horizontally behind the lens. A modern streak camera photograph of a 12-stroke lightning flash is shown in Fig. 16.2. A streak camera photograph of a stepped leader and the resultant return stroke is shown in Fig. 16.3. As is evident, the stepped leader channel is photographically dark between steps and elongates itself by a new step each time it lights up. A detailed description of the stepped leader is given in Chapter 9 and the stepped leader's movement towards ground is illustrated in Figs. 9.1 and 9.2.

Bead or chain lightning is a visually well-documented phenomenon in which the lightning channel to ground breaks up, or appears to break up, into luminous fragments generally reported to be some tens of yards long. The beads are reported to persist longer than the usual cloud-to-ground discharge channel.

No reliable still photograph of bead lightning has been published in the literature. Further, it is not clear that a still camera would record a beaded effect. If the channel is first continuous and then breaks up into beads, the image on the film will be a superposition of the continuous channel and the beads. The beads will only be apparent if the light output of the beads to which the film is sensitive is at least a small fraction of the light output of the channel prior to the formation of beads and if the film is not over-exposed.

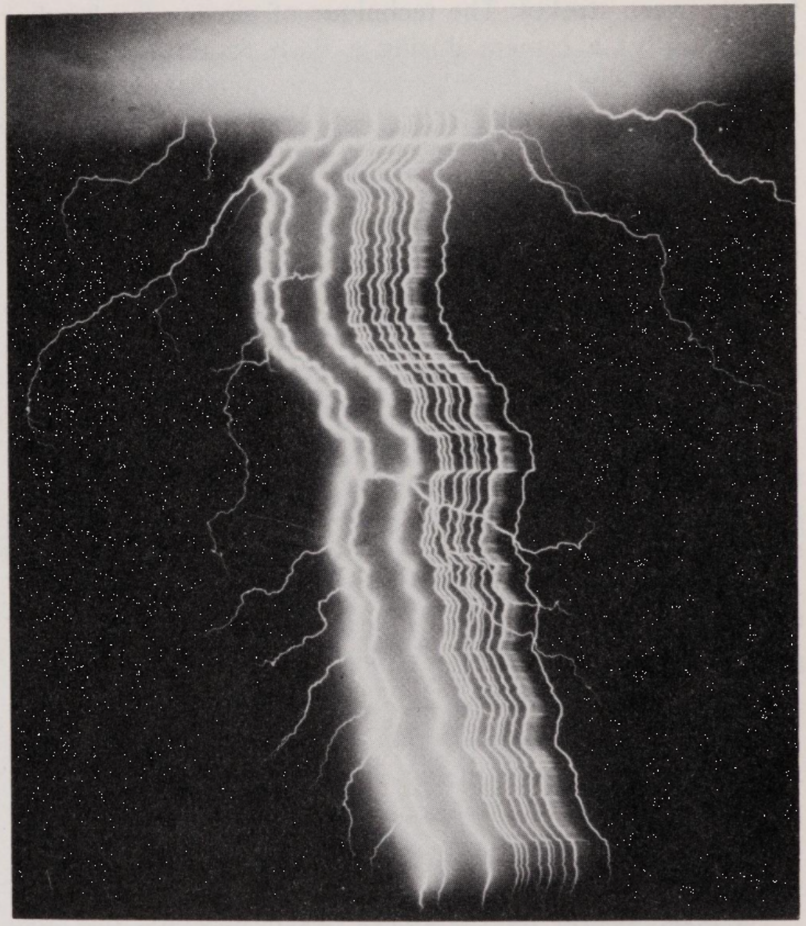

Fig. 16.2. Streak-camera photograph of a 12-stroke lightning flash taken near Socorro, New Mexico. The first stroke is on the left and is the only branched stroke (see Chapter 9). Increasing time goes from left to right. Continuing current (see Chapter 5), as evidenced by continuing luminosity, flows after the eleventh stroke. (Courtesy, Marx Brook, New Mexico, Institute of Mines and Technology)

To document bead lightning adequately, a movie is probably necessary. Figure 16.4 is a frame from one such movie taken by U. S. Navy personnel while photographing a plume of water rising from a depth charge explosion (Ref. 16.1). The lightning flash of Fig. 16.4 which struck the depth charge plume consisted of three strokes, the first lasting more than 0.5 second, the second about 0.1 second, and the last more than 0.1 second. Continuing current (see Chapter 5) was apparently involved in each stroke. The latter frames of each of the three strokes show a channel which has broken up into light and dark sections a few yards in length.

There are various theories of bead lightning and some of these are now considered:

(1) The visual appearance of bead lightning is caused by

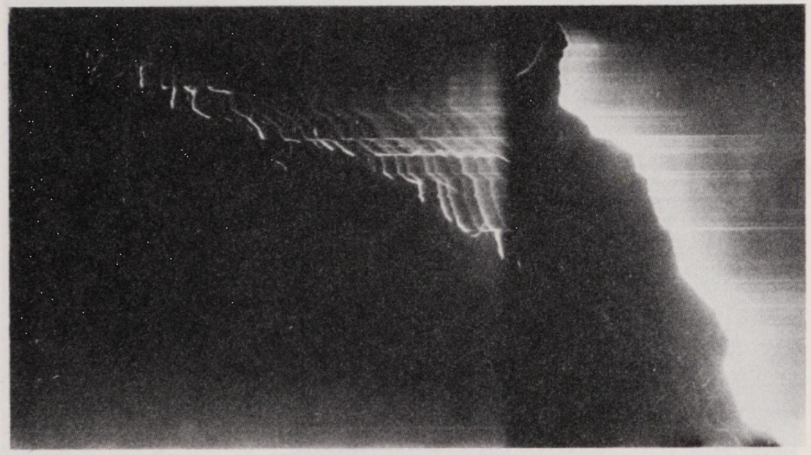

Fig. 16.3. Streak-camera photograph of a stepped leader and the resultant return stroke taken near Lugano, Switzerland. Increasing time goes from left to right; the time duration of the photograph is about 0.002 sec. The vertical height shown is about 400 yards. On the left side of the photograph the intensity of the leader is greatly enhanced. This enhancement was accomplished in printing the photograph in the darkroom. The right side of the photograph gives some idea of the relative brightness of the stepped leader compared to the return stroke. (Courtesy, Karl Berger, Eidg. Technische Hochschule, Zürich)

viewing portions of the lightning channel end-on. That is, if the lightning channel is coming toward or going away from an observer, the observer will see a greater length of the channel within a given viewing angle than would be the case were the channel perpendicular to his viewing direction. The greater length of channel appears to the eye as a normal channel of greater-than-normal brightness. To account for the beaded effect, the channel must periodically be slanted toward or away from the observer.

(2) Bead lightning is due to the periodic masking of a normal cloud-to-ground channel by clouds or rain.

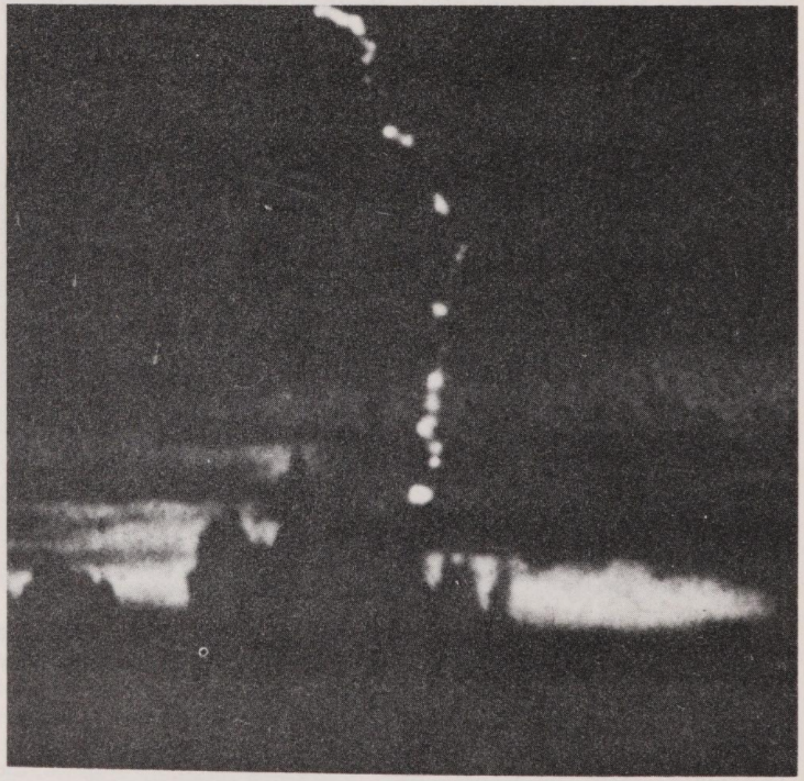

Fig. 16.4. Bead lightning as it appears on one frame of a motion picture showing a three-stroke flash striking the top of a depth charge plume. (Courtesy, U.S. Naval Ordnance Laboratory)

(3) A "magnetic pinch-effect" instability may distort the current-carrying channel into a "string of sausages" with the strong light emission coming from the "necked-off" regions of high-current density. To obtain a series of beads this way, the channel must somehow be conditioned periodically as a function of height. Possibly, the periodicity is just an accident of nature.

(4) Bead lightning is a series of ball lightnings (see Chapter 15).

(5) Large-radius sections of the lightning channel have long luminous lifetimes since channels of large radius take longer to cool than channels of small radius. To a first approximation the cooling time is proportional to the square of the radius. If the lightning channel radius were somehow periodically modulated as a function of height, then, as channel luminosity decayed, the channel would take on the appearance of a string of beads. Perhaps this modulation occurs accidentally when the channel consists of a large number of kinks or bends.

To account for the observed long persistence of the beads, those theories which require current flow may be invoked in conjunction with long continuing currents. Perhaps the observed long persistence is due to the eye rather than to the channel.

A comprehensive discussion of lightning photography including several streak-camera photographs and references to published photographs of ribbon lightning is given in *Lightning,* Chapter 2.

chapter seventeen

Has Lightning Any Practical Use?

Energy is neither created nor destroyed. Rather, it is converted from one form to another. For example, in a light bulb the input electrical energy is converted to light and heat. The energy content of the output light and heat equals that of the input electrical energy. No energy is lost. A charged thundercloud contains stored electrical energy derived from the energy of winds and particle motions and from the energy released by condensing water vapor (see Chapter 7). Some of the stored electrical energy of the cloud is transferred to lightning. We consider now the energy and power available to lightning and the possibility of its controlled use for the benefit of man.

Each cloud-to-ground lightning flash involves tens of coulombs of charge (see Chapter 8) at a voltage of between 100 million and a billion volts. The resultant electrical energy is about 1 to 10 billion watt-seconds per flash. If there are 100 flashes to ground each second over the whole world (see Chapter 7), a maximum value for the total electrical power input to worldwide cloud-to-ground lightning is 1,000 billion watts. By comparison, the total capacity of all electric power generators in the United States in 1970 was about 500 billion watts. It is evident, therefore, that the power and energy available to lightning is appreciable.

Unfortunately, no efficient method of tapping lightning's power and energy is presently available – for two reasons: (1) It is impractical to intercept (for example, with tall towers) any significant number of the world-wide cloud-to-ground flashes. (2) Most of the energy available to the lightning is converted along the lightning channel to thunder, heat, light, and radio waves, leaving only a fraction available at the channel base for immediate use or storage.

The first problem is the more serious. If its total energy were available, a *single* lightning flash would run an ordinary household light bulb for only a few months. It is the high rate of occurrence of world-wide lightning (100 per second) which provides for the high total power and energy levels. A 1000 ft tower in a region of moderate thunderstorm activity is struck by lightning about 10 times a year (see Chapter 6). It would take one hundred thousand such towers, each collecting all the energy from ten strokes per year, to equal the 100 million watts generated by a typical small power station. It is impractical to erect a sufficient number of towers to capture significant quantities of energy from lightning, and no more practical means of intercepting lightning has been proposed.

Ancient man considered lightning the ultimate weapon. Its use and control were generally attributed to the gods. The Norse god Thor hurled lightning from his chariot while riding across the sky. In ancient Greece, Zeus threw the thunderbolts; in Rome, Jupiter. The advent of our modern civilization has not eliminated man's interest in the use of lightning as a weapon. Military research in several countries has recently been concerned with the feasibility of directing lightning and ball lightning at specific targets. While technology is not capable of achieving these goals at present, it would not be surprising if they were attained in the not too distant future. In view of the awesome destructive power of modern weaponry, the military use of lightning or ball lightning would probably be more as a psychological than as a destructive weapon.

Nitrogen comprises about 80% of the atmosphere surrounding the earth, yet it cannot be used directly by the large majority of plants and animals until it is "fixed." "Fixed" nitrogen is nitrogen incorporated in chemical compounds necessary to the chemical processes of life, as opposed to the relatively inert form of nitrogen, the nitrogen molecule, found in the air. Fixing is accomplished by (1) special organisms in the soil and waters, (2) industrial processes, and (3) ionizing atmospheric processes including lightning. Nitrogen which has been fixed in the atmosphere is brought to earth in rain. It has been estimated that of the 100 million tons of nitrogen fixed per year, about 8% is atmospheric, about 30% industrial, and the remainder biological (Ref. 17.1). Estimates of this sort are difficult to make and subject to large errors. The role played by lightning in generating fixed nitrogen is frequently accorded prominence in the popular literature. We can, however, show that lightning is not as important in nitrogen fixing as is generally believed.

About 8 million tons of fixed nitrogen are thought to be brought to earth each year in rain. If we assume that (1) there are 500 lightning discharges (cloud-to-ground and intracloud) occurring each second (see Chapters 7 and 8), (2) each lightning channel is 2 in. in diameter and 4 miles long (see Chapter 10), (3) every nitrogen atom in every channel is "fixed" (a great overestimate), then the total amount of nitrogen fixed by the lightning channels is about 20,000 tons per year. Since 20,000 tons is a very small fraction of 8 million tons, we conclude on theoretical grounds that the lightning channel itself is not an important producer of fixed nitrogen. Experimental evidence to support this conclusion has been given by several investigators (Refs. 17.2 to 17.5) who show that the nitrate and ammonia content in precipitation is not correlated with the amount of lightning activity. In fact, there is roughly the same nitrate and ammonia content in precipitation in winter when there are few thunderstorms as in summer when there are many (Ref. 17.2). What, then, is the source of the atmospheric nitrogen compounds? The answer is not known, but there are two reasonable possibilities: (1) They are generated in the lower regions of the ionosphere (the ionized layer of atmosphere beginning about 40 miles above the earth) and diffuse downward, and/or (2) they are created by corona discharges in all types of precipitating clouds and along the ground under those clouds (Ref. 17.5). If possibility (2) is important, a close relative of lightning has contributed and continues to contribute significantly to the world's fixed nitrogen supply.

The lightning channel generates radio waves (sometimes called atmospherics or sferics) which have been used for practical purposes. Lightning is the strongest terrestrial source of electromagnetic noise in the radio band. The lightning radio noise is strongest near a frequency of 5 kilocycles per second and extends with decreasing intensity up and down the frequency scale as far as has been measured. Everyone is familiar with the lightning static produced on AM radios and the "snow" on TV pictures (particularly on the lower channel numbers) due to lightning radiation. Studies of the lightning electromagnetic noise have led to several practical applications. (1) Measurements made on lightning radio waves can be used to pinpoint the location of the thunderstorm area producing the lightning. Among those who use this information are meteorologists (who study as well as predict the weather) and aircraft pilots. Radiolocation techniques can spot thunderstorms thousands of miles away. (2) Measurements of the properties of lightning radio waves returned from the ionosphere and from ionized layers above the ionosphere have yielded valuable information about the numbers and kinds of charged particles in those regions. (3) Measurements of the properties of lightning radio waves as they propagate along the earth's surface have enabled the electrical resistivity of various portions of the earth to be determined. Similarly, lightning radio waves can be used in some kinds of geophysical prospecting (e.g., in the search for low resistivity ore lying far below the earth's surface).

chapter eighteen

What Would Happen If Lightning Were Eliminated?

First, it is appropriate to point out that it may well have been lightning in the primordial soup covering the earth several billion years ago that produced the complex molecules from which life eventually evolved. Laboratory experiments have shown that electrical discharges in what is believed to be the constituents of the primordial atmosphere can create the necessary molecules. Thus, we may be indebted to lightning for the presence of life on earth.

Still, lightning is primarily troublesome rather than helpful, as the contents of this book attest, and except for some of the benefits mentioned in the previous chapter it might seem advantageous to eliminate it altogether. Exactly what would happen if lightning were eliminated is not known, but clearly the electrical balance of the atmosphere would have to change as we shall see in the following paragraphs. If and

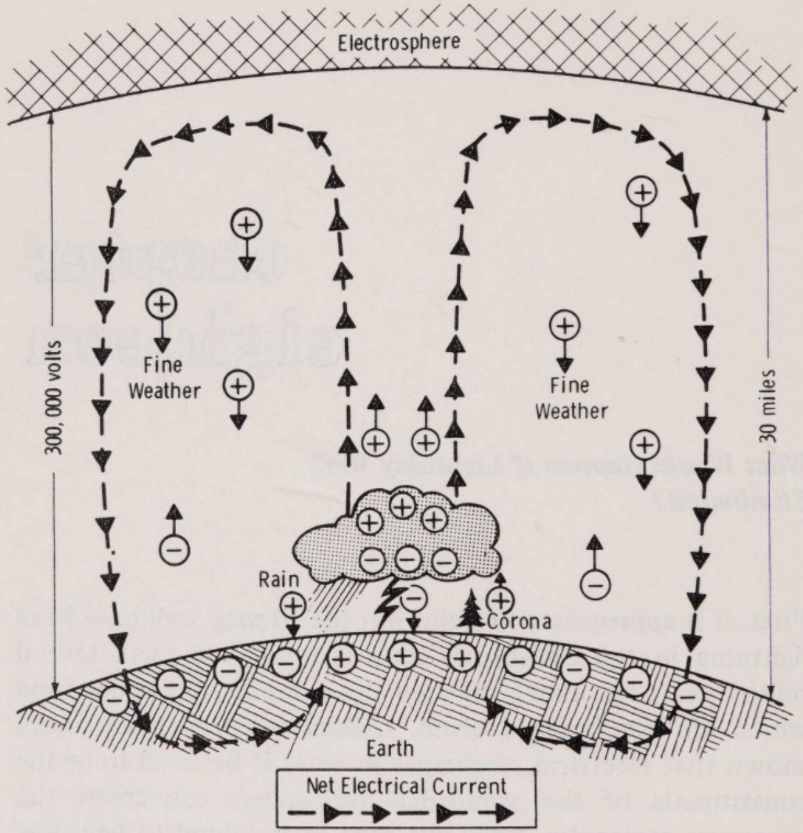

Fig. 18.1. Thunderstorms act as batteries to keep the earth charged negatively and the atmosphere charged positively. Atmospheric electrical currents flow downward in fine weather and upward in thunderstorms. Thunderstorms deliver charge to the earth by lightning, rain, and corona discharges.

how the change in electrical balance would change the weather is not known. Prudence, however, would dictate extreme caution in tampering with lightning.

The electrical resistivity of the atmosphere decreases with height. From the point of view of atmospheric electricity, the resistivity is sufficiently low at an altitude of about 30 miles that the voltage does not vary much above that point. The region beginning at about 30 miles and extending upward is called the *electrosphere*. (The ionosphere, which reflects lightning radio waves downward, begins, as noted in Chapter 17, at about 40 miles and is even a better conductor than the bottom of the electrosphere.) The voltage between the earth and the electrosphere in regions of fine weather is about 300,000 volts. To maintain this voltage the earth has a negative charge of about a million coulombs on its surface and an equal net positive charge is distributed throughout the atmosphere. Measurements have shown that the negative charge on the earth remains roughly constant with time. At first glance, this fact is difficult to understand since the charge on the earth is continuously leaking off into the conducting atmosphere. In fact, calculations show that, if the earth's charge were not being continuously re-supplied, the charge on the earth would disappear in less than an hour.

The earth is recharged by thunderstorms. Fig. 18.1 shows how the electrical balance of the atmosphere is maintained. Thunderstorms deliver a net negative charge to the earth as a result of the sum of the effects of the following processes: (1) negative charge carried from cloud to earth by lightning, (2) positive charge carried from cloud to ground by rain, and (3) positive charge carried upward (the equivalent of negative charge carried downward) through the air beneath and above a thunderstorm, the source of the positive charge being corona discharge off grass, trees, and other objects with sharp points on the ground beneath the thunderstorms. The total current flowing beneath all thunderstorms in progress

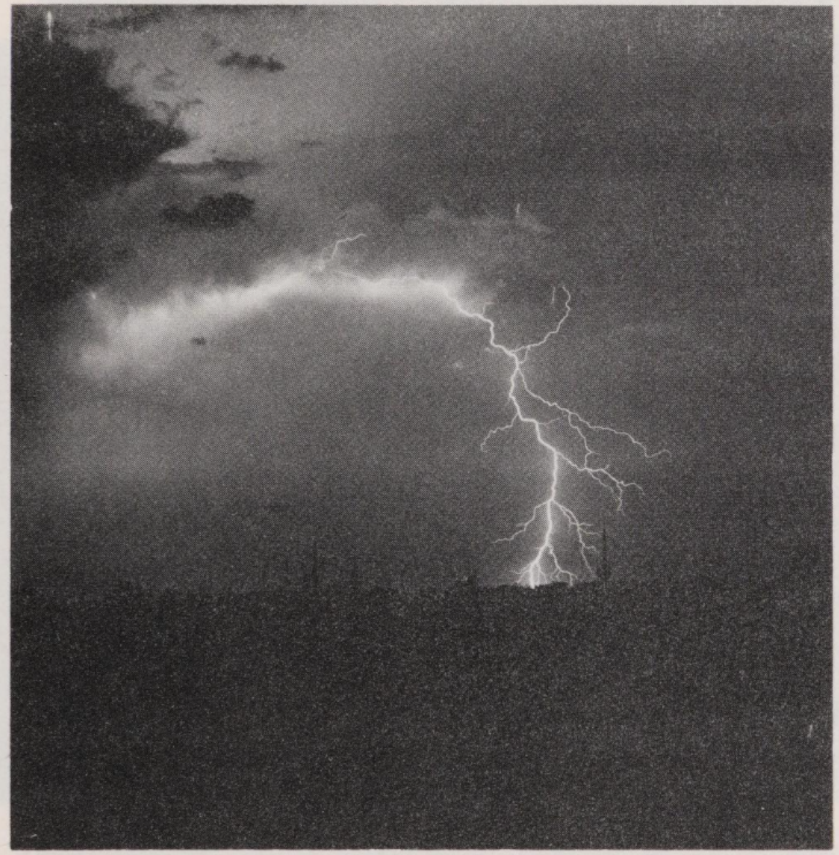

Fig. 18.3. Lightning over the Arizona desert. (Courtesy, J. Rodney Hastings, University of Arizona)

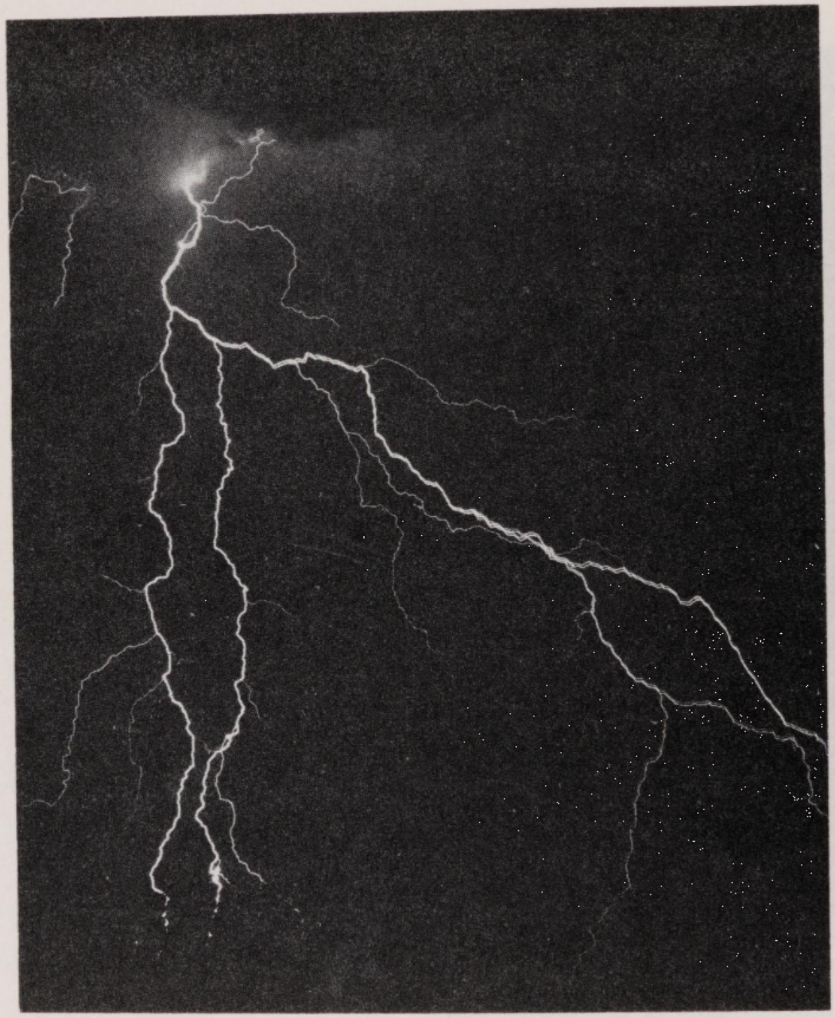

Fig. 18.4. A lightning flash exhibiting multiple ground points and the ribbon effect discussed in Chapter 16. (Courtesy, George Marcek, Catalina High School, Tucson)

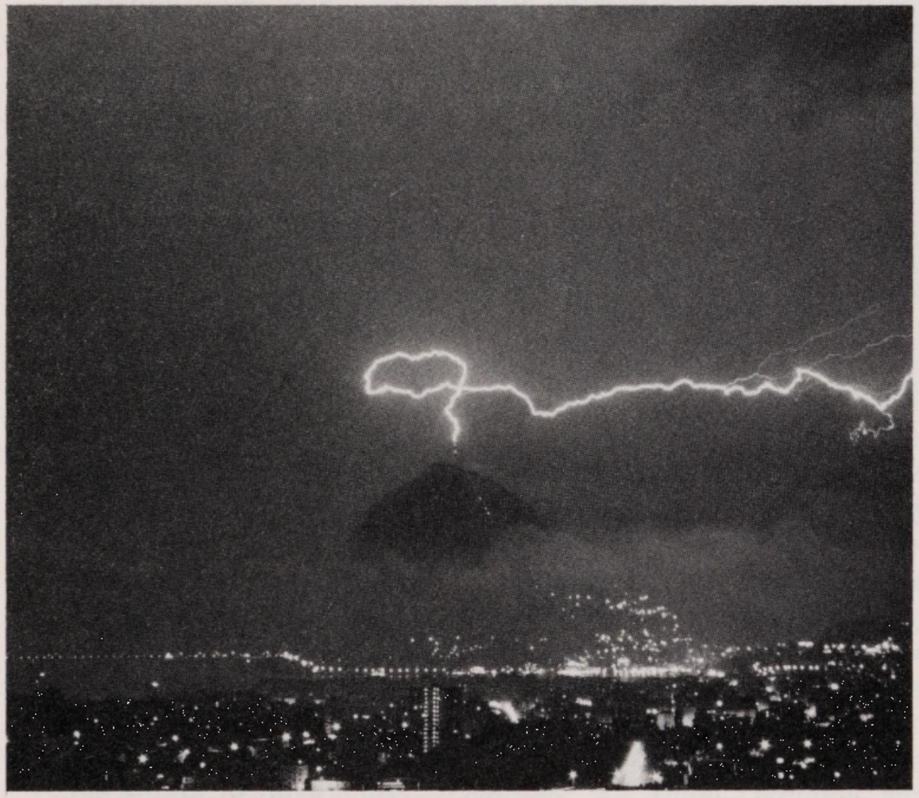

Fig. 18.5. Lightning initiated by an upward-moving leader from a tower on Mt. San Salvatore near Lugano, Switzerland. Photographs of other discharges to the tower are shown in Fig. 6.1a, b. (Courtesy, Richard E. Orville, State University of New York at Albany)

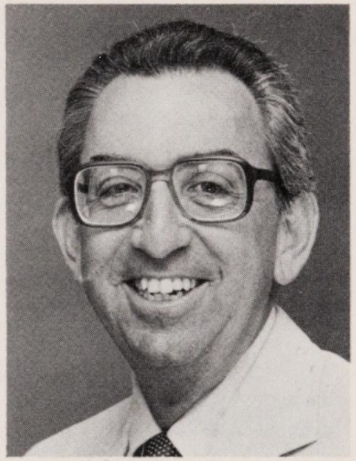
throughout the world at any given time is thought to be about 2000 amps, and is in such a direction as to charge the earth negatively. An approximately equal and opposite current flows in regions of fine weather. The result is that the net negative charge on the earth and the equal and opposite net positive charge in the atmosphere remain approximately constant.

Finally, if all lightning were eliminated, we earthly viewers would be deprived of one of the most spectacular visual displays that Nature has to offer. In its variety and brilliance lightning puts man-made fireworks to shame, as evidenced by Figs. 18.2 to 18.5. Watching lightning is fun; one of the aims of this book has been to make it more so. Many confirmed lightning watchers even enjoy listening to the variety of sounds that comprise thunder.

REFERENCES

The details of and references to the bulk of the material found in this chapter are to be found in *Atmospheric Electricity*, J. A. Chalmers, 2nd Edition, Pergamon Press, New York, 1967, pp. 33-35, 292-308.



Martin A. Uman received the B.S.E. degree in electrical engineering in 1959 from Princeton University, where he was elected to Phi Beta Kappa. After receiving his Ph.D. from Princeton University in 1961, he took a post as Associate Professor of Electrical Engineering at the University of Arizona, where he became interested in lightning research, particularly in lightning spectroscopy. In 1965, Dr. Uman moved to the Westinghouse Research Laboratories in Pittsburgh, where he continued his lightning research and, in addition, studied the electrical, optical, and acoustic properties of long laboratory sparks. He has been Professor of Electrical Engineering at the University of Florida since January 1972, where his primary research interest has been in the electromagnetic radiation produced by lightning. In 1976, Dr. Uman and Dr. E. P. Krider, Professor of Atmospheric Sciences at the University of Arizona, formed Lightning Location and Protection, Inc. (LLP), a small company that specializes in consulting on unusual lightning problems and manufacturing lightning detection equipment. Dr. Uman served as president of LLP from 1976 until 1983. Dr. Uman is the author of three books—*Lightning, All About Lightning,* and *Introduction to Plasma Physics*—and approximately 85 journal articles, and has served as Associate Editor of the *Journal of Geophysical Research.* He is a member of the International Commission on Atmospheric Electricity, the American Geophysical Union, and the IEEE, and is a fellow of the American Meteorological Society.

ALL ABOUT LIGHTNING

Martin A. Uman

". . . contains a surprising wealth of well-organized, authoritative information about lightning."—Bulletin of Amer. Meteorological Society

Does lightning strike twice in the same place? How does a lightning rod work? What is ball lightning? How many thunderstorms are in progress in the world at any one time? Why does lightning zigzag? What is St. Elmo's Fire?

These and many more often-asked questions about lightning are answered in this fascinating and informative guide for the layman, presented in an easy-to-follow question-and-answer format. One of nature's most awesome phenomena, lightning has intrigued man since earliest times. In this book, a noted scientist and expert on lightning dispels many misconceptions while offering a wealth of scientific and technical information about the nature of lightning and its effects.

You'll discover how Benjamin Franklin proved that lightning was electrical, how to protect yourself from lightning, how to photograph lightning (it's not difficult), the possible relationship between ball lightning and UFOs, what to do for a person struck by lightning, the nature of sheet lightning, ribbon lightning, bead lightning and other variations, and much more. While the overall approach is nontechnical, Dr. Uman has incorporated scientific data in the answers in such a way that laymen will find the book a near-painless introduction to current scientific knowledge about lightning.

Simple, well-drawn diagrams illuminate the text, along with a selection of spectacular lightning photographs, including a remarkable image of 5 lightning bolts produced by the explosion of the first thermonuclear device. In addition, each chapter contains a list of references cited in the text which suggest further reading for anyone interested in finding out more about earth's dazzling atmospheric fireworks.

Unabridged, corrected Dover (1986) republication of *Understanding Lightning*, published by Bek Technical Publications, Inc., Carnegie, Pa., 1971. Preface. 16 black-and-white illustrations. 27 black-and-white photos. Color photos on covers. Bibliography. Index. 192pp. 5⅜ × 8½. Paperbound.

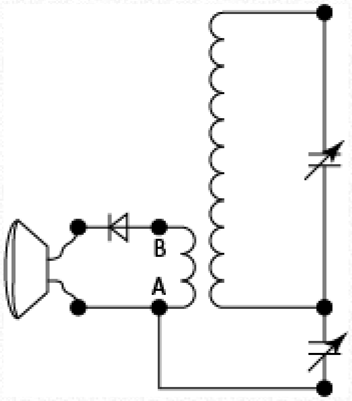
Loop Antenna Crystal Radio

C2
Sr. Member



View attachment 15935 I built a fully integrated loop antenna crystal radio on a 23" diameter form (one slat of plastic/wood window blind). I like it because it is completely portable and does not require any additional antenna.

11 turns form the primary and 3 turns the secondary, small gauge phone line stranded copper, all close wound. All turns work out to about 1/2" wide. The primary currently measures 216 uH and I think the secondary was around 40 uH (I'll check this again as I think it was actually much lower, like 16 uH even).

I used a dual gang 15-400, 12-200 pF air variable capacitor. I tried connecting the 12-200 to either point A or B, or not at all. Point B gave about 2 uA more current in the secondary and Point A about 2 uA more again, so I left it at point A.

It tunes from a little over 600 kHz to a little over 1800 kHz. I'm able to pick up 10 stations and the antenna is highly directional, I can completely null the strongest station by turning the loop in-line to the station. The strongest station produces 18 uA in the secondary. What is interesting to note, however, is that I was using an RF generator to find the limits with its output into an open wire loosely wrapped around the antenna. It might be the generator output, but the 600 kHz resonance point produced much less current (~60 uA) than the top end.

I would like to lower its response by 100 kHz. Any suggestions? I was thinking of adding a turn or two to the primary, but given the note above, I'm not sure if something else would be more appropriate?

I added one more turn to the primary and that brought the frequency response from 540 to 1700 with increased sensitivity at the low end.

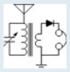
Loop-Stick Crystal Set

Post Reply | Search this topic… | 16 posts ‹ 1 **2**



Dan McGillis

Mon Jan 26, 2009 12:52 pm

Hi all.

I used this little loop-stick radio in the just-ended ‘09 Crystal Radio DX contest. Wanted to see how it would do as a simple double-tuned rig.

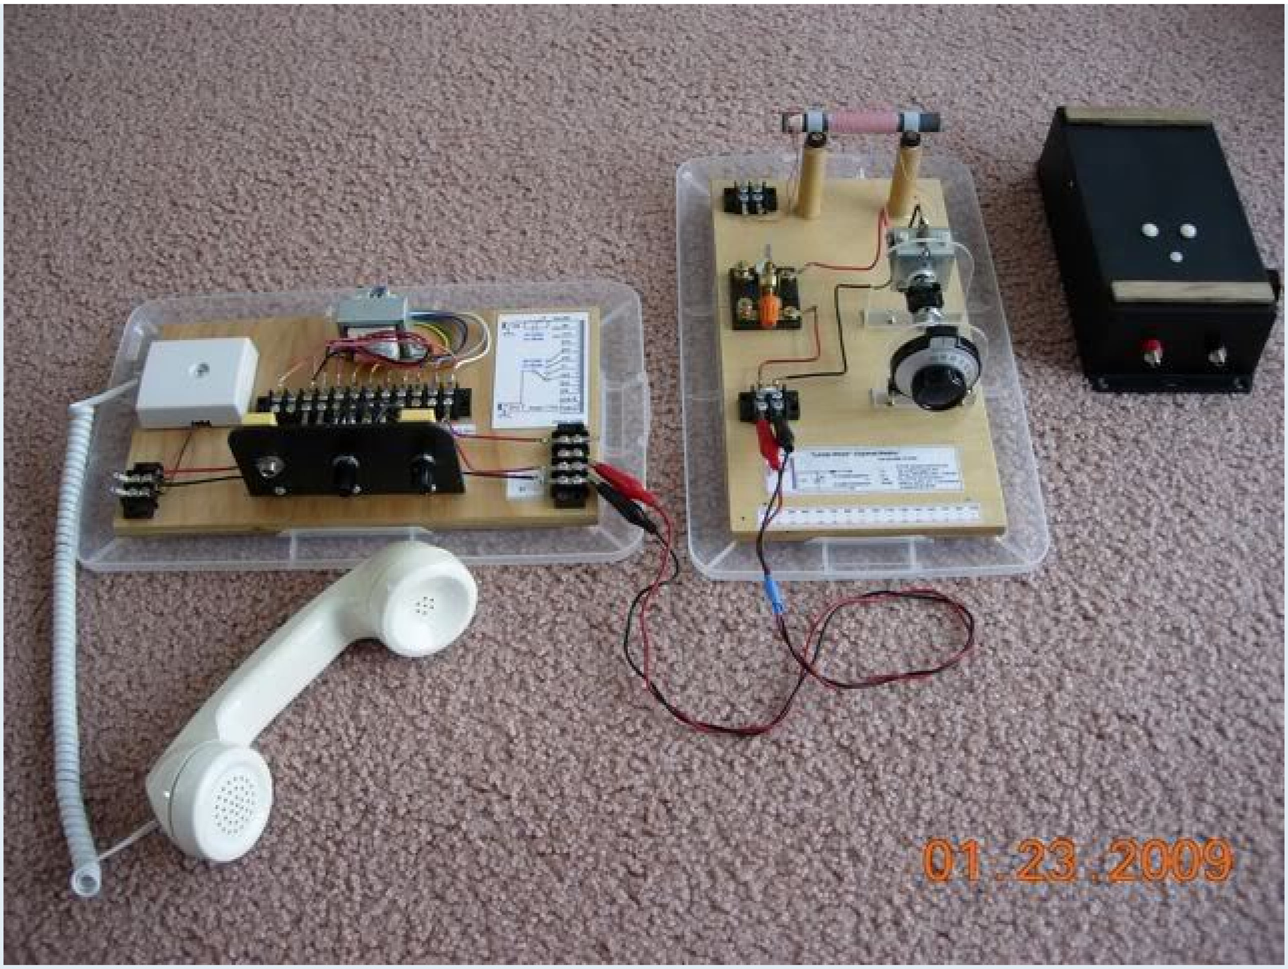
Not too bad: 84 stations ID’d in about 13 hrs of listening time.
-------A big old 200’ antenna certainly helps a bit 🙂

This setup makes a nice progressive radio for the grandkids (& grandpa):

- start out with the basic cat’s whisker detector (thanks Mike),
- add a good FO-215 diode,
- add a Bogen+Benny for some audio matching,
- add an antenna tuner,

and you wind up with a decent little set.

Here’s a picture.



Fun stuff.

Loop-Stick Crystal Set

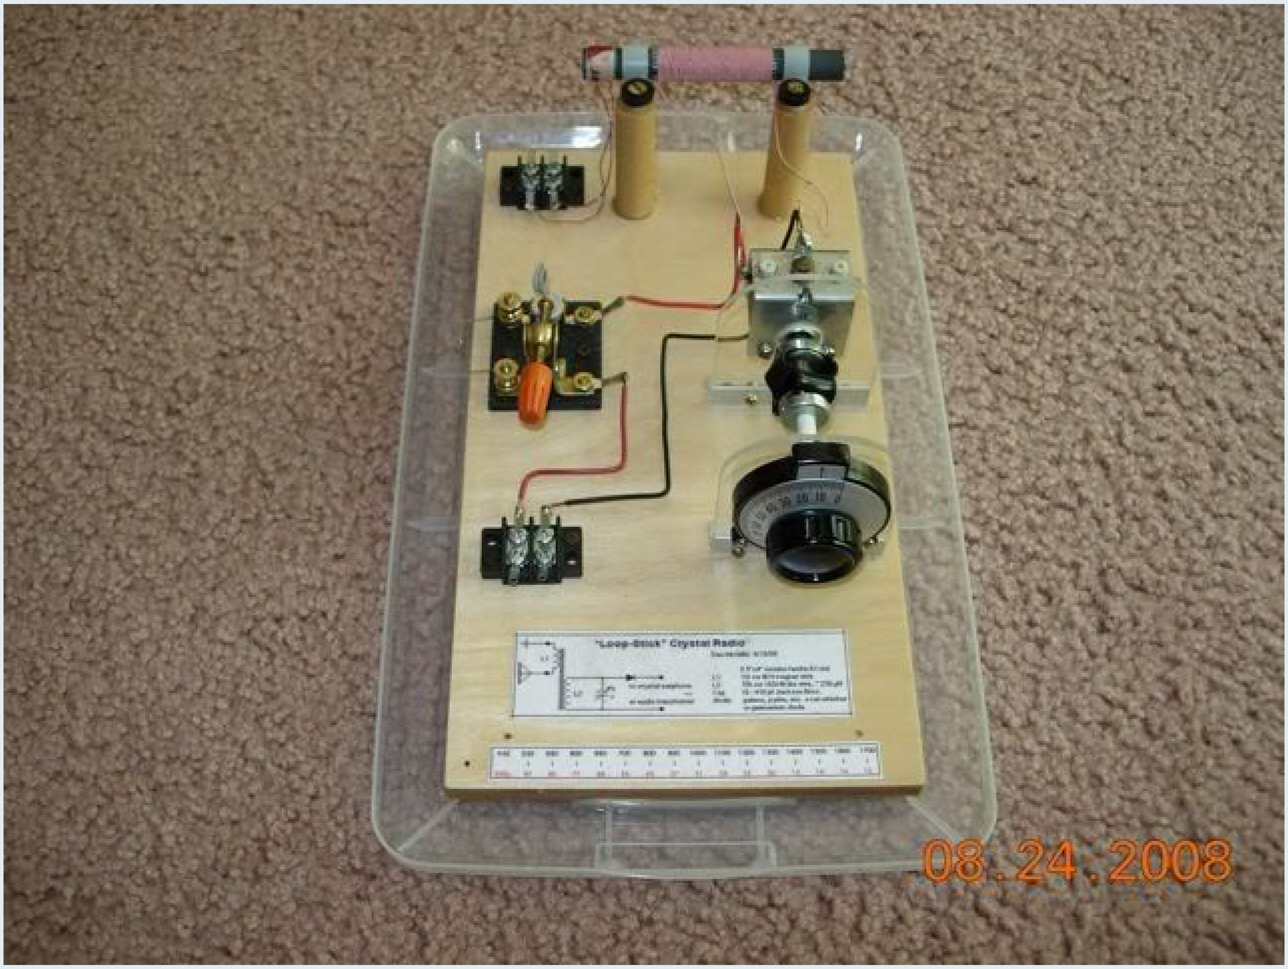
Fri Sep 26, 2008 2:25 pm

I wanted a simple crystal set that would highlight Mike Peebles' rock stand ('cause I really like it) and one that could serve as a nucleus for a project radio. This little "loop stick" radio seems to be just the ticket.



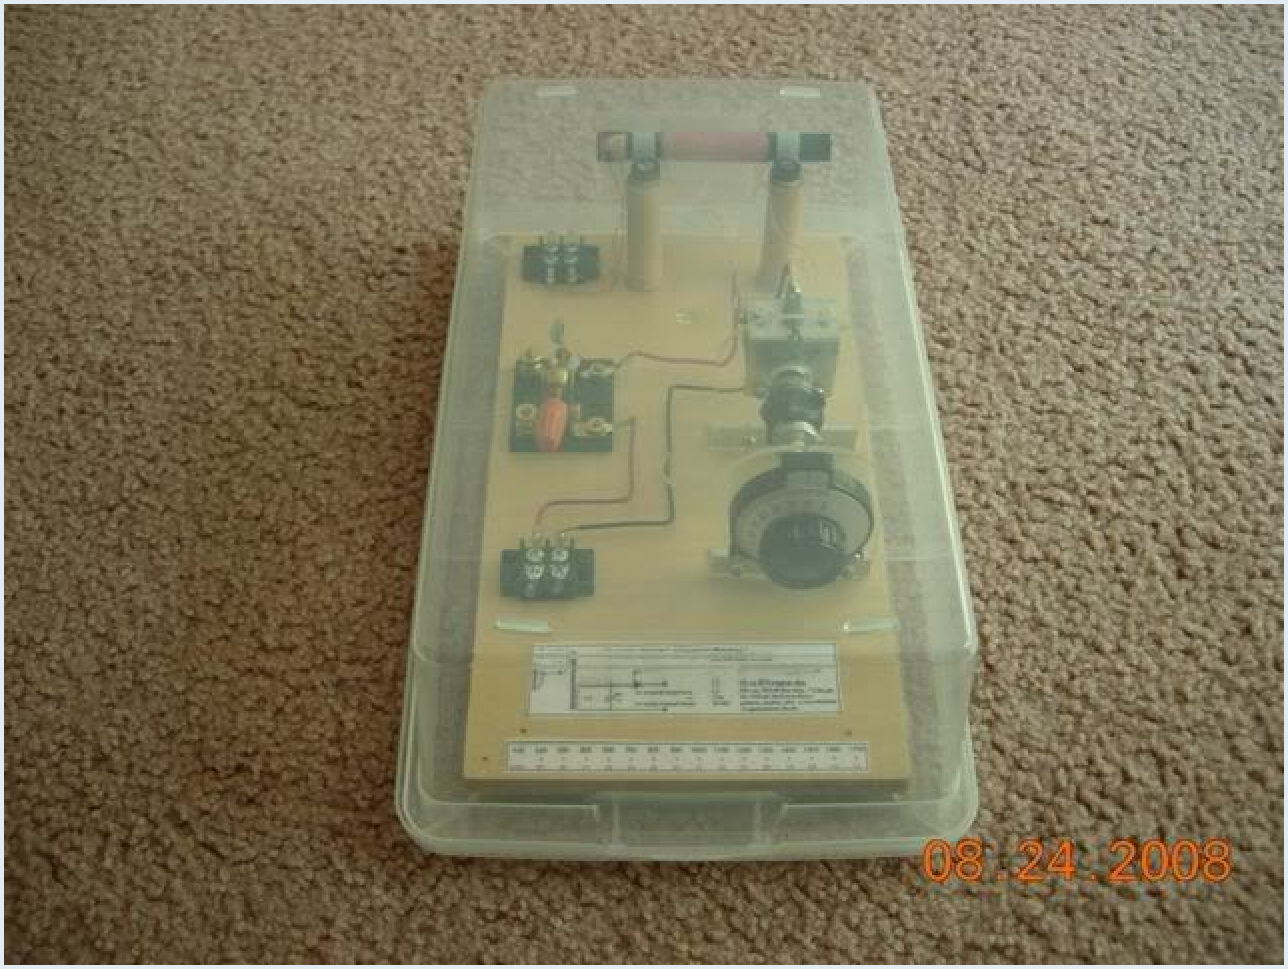
0.5"x4" Amidon ferrite-61 rod,
10t cw #24 magnet wire for the antenna coupling coil,
55t cw 165/46 litz (about 230 uH),
10-410 pf Jackson Bros. capacitor,
Peebles rock stand + crystal, or a diode.

The antenna-ground is connected at the top terminal block and the audio comes out the bottom terminal block.

It works pretty good by itself with a piezo earpiece. But it really perks-up when some bells & whistles are added. Like an antenna coupling capacitor, and/or a Bogen+Benny at the output, and/or a sensitive headset, and/or a loose coupled antenna tuner, etc., etc.. It's kind of fun to fiddle around with it.

A problem I've always had is DUST. I'm banished to the basement for crystal set work and the sets seem to accumulate a thick coating of dust in short order if they're not covered-up. But I wanted this little setup to be out in the open so the grandkids could see it & maybe increase their interest in radio. (It's hard to compete with video games!)

I found some $1.50 clear plastic storage boxes - with lids - at Bed Bath & Beyond that make nice dust covers. The radios' wooden base is screwed to the inside of the lid and the box part then sits on top. No dust on the parts and you can see the inner workings through the plastic. 🙂 The inside clearance is almost 4" so there's plenty of room in there - especially if ferrite-assisted coils are used.



Not elegant, but it works.

Fri Sep 26, 2008 3:38 pm

heh, great idea and a good looking set,
I store my competition rig (ATU, detector unit, Phones, ultimatch2...) in a similar box, just MUCH larger (22liters), no

wooden base screwed to the top, just store.
I also use the box as table for the rig in use (it is Poly Propylene so low loss at RF).

Does anyone know why production loopstick antennas are multi layered?

Ham-er

loopstick layering

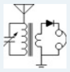
Tue Sep 30, 2008 11:53 pm

> **homebrew wrote:**
> Does anyone know why production loopstick antennas are multi layered?

Good question Homebrew,

My best guess is cost(maunfacturer being cheap). As most of the commercial "loopstick" are probably intended to go into cheap transistor superhet desing radio,s, the loopstick doesnt need the best Q or efficiency.
In these sets the selectivity is controlled by the IF stage, and the sensitivity by amplification either in the RF amp if it has one, or the converter transistor if not, and by the AGC.

Can anyone verify my guess?

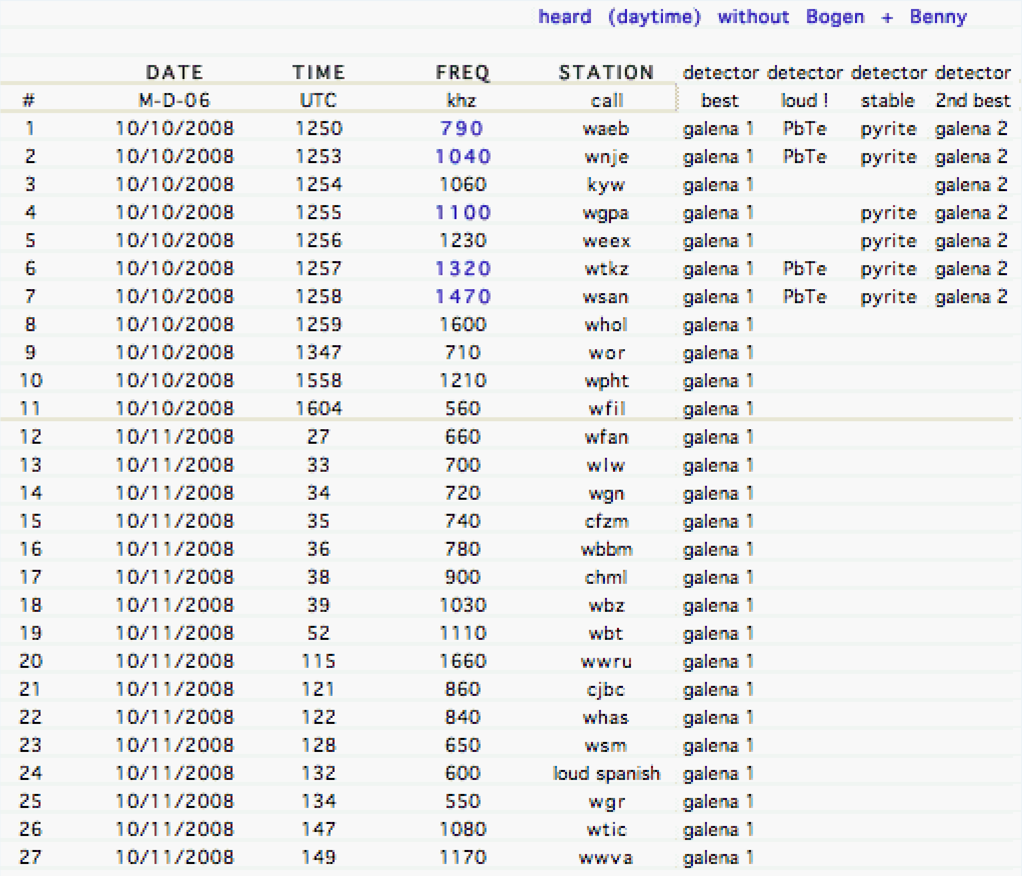


Dan McGillis

Tue Oct 14, 2008 12:45 am

To complete the story - I used the little loop-stick radio in the just finished ‘08 Sprint contest. It was single tuned (no antenna tuner) and no diode was used - only “crystal” detectors, primarily galena. Kyocera KBT-44SB-1A piezo elements made-up the headset. I did put a variable capacitor in the antenna line to vary the coupling.

The log is shown below:



heard (daytime) without Bogen + Benny

	DATE	TIME	FREQ	STATION	detector	detector	detector	detector

Although I didn’t spend a lot of time listening, this simple set will bring-in a lot of stations.

The 2 close-by stations (10 km @ 3.6kW & 11 km @ 5kW) are VERY loud -- just right for a grandkids' first taste of crystal radio. Adding a coupling capacitor to the antenna line tamed the "flame-throwers" a bit and then more stations could be heard.

At night, DX stations were strong and in-the-clear. Easy,pleasant listening.

The detector stands' whisker adjustment was smooth and very stable -- even a grandpa could do it 😉 When a VERY light contact to the crystal was achieved, the set's selectivity improved greatly. A heavier hand produced broader signals. The effect was dramatic to hear.

The addition of a Bogen + Benny makes a worthwhile improvement -- as everyone here knows.

As-is, it's a kid-friendly, easy to operate, well behaved little set.

When a decent (high Rd) diode like an FO-215 replaces the crystal detector, and an antenna tuner coil - like the one at

viewtopic.php?t=1132

is loosely coupled to the set - there's DX all over the dial. Fun stuff.

73, Dan

yah dont have camra yet till after holidays but think out side the ciggar box a varyo copler w tuner selector {tikler coyle} wt optional
det/amp/set three peace 😉 ciggar box S.E.T. amp is done with feed back gitar amp neatly hidden in ciggar box witth feed back
controle gain vol for 20 ohm all tgether new sp set.stil working on
other half took 1 ciggar left the rest @ nebors rpm shop for his cellibrations the amps not going to be entrd on contest but a
fools gold piyrite det mated with tuner will be.
feed back by the way on gitar amp. works well with tune n det. sets eavin after trans former and ceramic disc cap. ❓
just good gon rite idea i gess 😳 might turn old amp box to all together new set or rf osc or somthinng. radio bord is new

Loose Coupler Set

In spring of 2016, I decided to build a crystal set with my friends. After searching information on the net, I found a series of introductory videos shown in MICROWAVE1 channel on YouTube very interesting. So, I designed a set based on the loose coupler in the video and added antenna tuning and the detector circuit.

The sliding notch of the antenna coil was not well-made or smooth, but once its position is set, it works fine. The move of secondary coil is also not satisfactory, but I have no complain. You need to reach the slider and the moving coil behind the front panel, so it is a bit annoying. With S4, *DP3T, you can make connection of the coil and capacitor serial or parallel. Rotary switches, S5 and S6 are *SP6T to select taps. Capacitance of the variable capacitors can be added by S2 and S7.

L1 and L2 use 0.5mm polyurethan coated wire and are wound on PVC pipes. R1 should be determined according to the phone(s) you use, or you can make it variable.

Finding the best settings is not so easy but very interesting. You need to adjust L1, L2, C1, and C2 simultaneously, little by little. With an 18 m long wire antenna around my house and a shallow ground earth, maximum voltage at the phone was 50-80 mV when tuned to local stations (10 kW / 10 km). It cannot pick up stronger but distant stations, such as the one with 300 kW at 200 km away, even at night. I may need longer and higher antenna for that.

This is not a super high performance set. It has OK sensitivity and not so great selectivity (no QRM though), but it outputs decent level of sound and certainly is fun to play with. Please note that all the evaluations are very subjective as I have no way to compare other ones.

July 15, 2016

*DP3T: Double pole 3 throw, SP6T: Single pole 6 throw

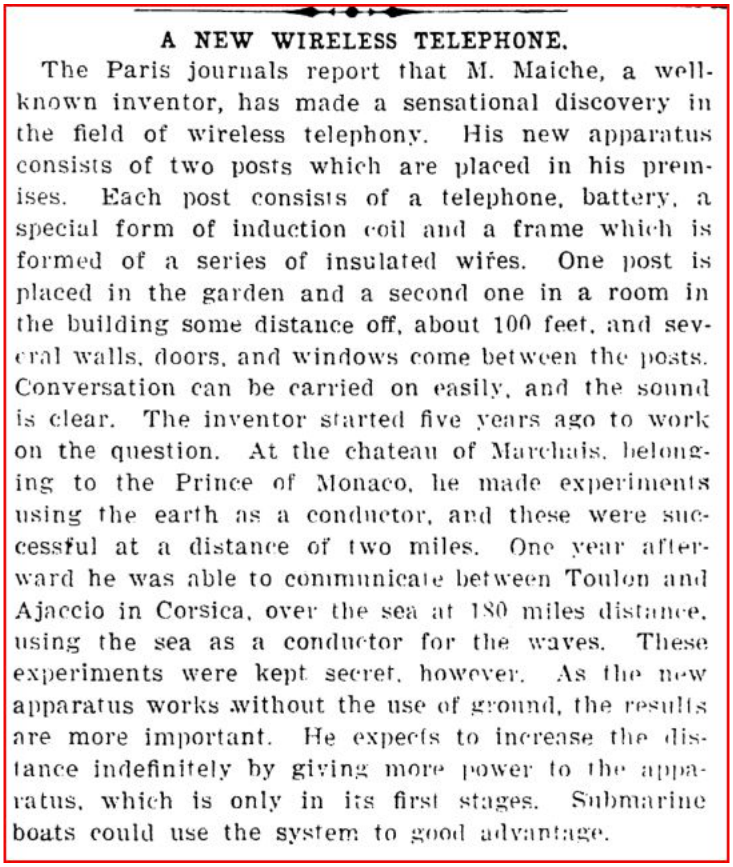
Sure, it looks silly now -- but wait until an EMP destroys the modern grid -- then you'll want/need this proven simple, inexpensive alt-tech earth-radio -- directional, low energy, & untappable -- and anyone can build it...

Jerry Vassilatos : Vril Compendium



A NEW WIRELESS TELEPHONE.

The Paris journals report that M. Maiche, a well-known inventor, has made a sensational discovery in the field of wireless telephony. His new apparatus consists of two posts which are placed in his premises. Each post consists of a telephone, battery, a special form of induction coil and a frame which is formed of a series of insulated wires. One post is placed in the garden and a second one in a room in the building some distance off, about 100 feet, and several walls, doors, and windows come between the posts. Conversation can be carried on easily, and the sound is clear. The inventor started five years ago to work on the question. At the chateau of Marchais, belonging to the Prince of Monaco, he made experiments using the earth as a conductor, and these were successful at a distance of two miles. One year afterward he was able to communicate between Toulon and Ajaccio in Corsica, over the sea at 180 miles distance, using the sea as a conductor for the waves. These experiments were kept secret, however. As the new apparatus works without the use of ground, the results are more important. He expects to increase the distance indefinitely by giving more power to the apparatus, which is only in its first stages. Submarine boats could use the system to good advantage.

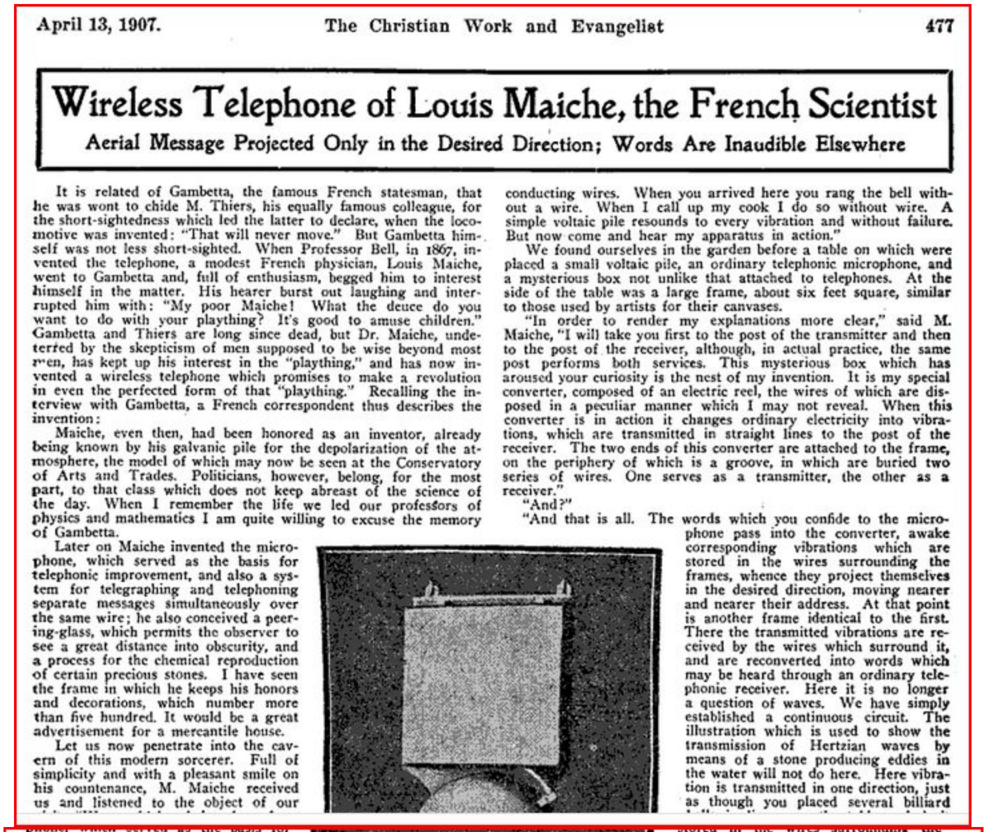
Wireless Telephone of Louis Maiche, the French Scientist



Wireless Telephone of Louis Maiche, the French Scientist

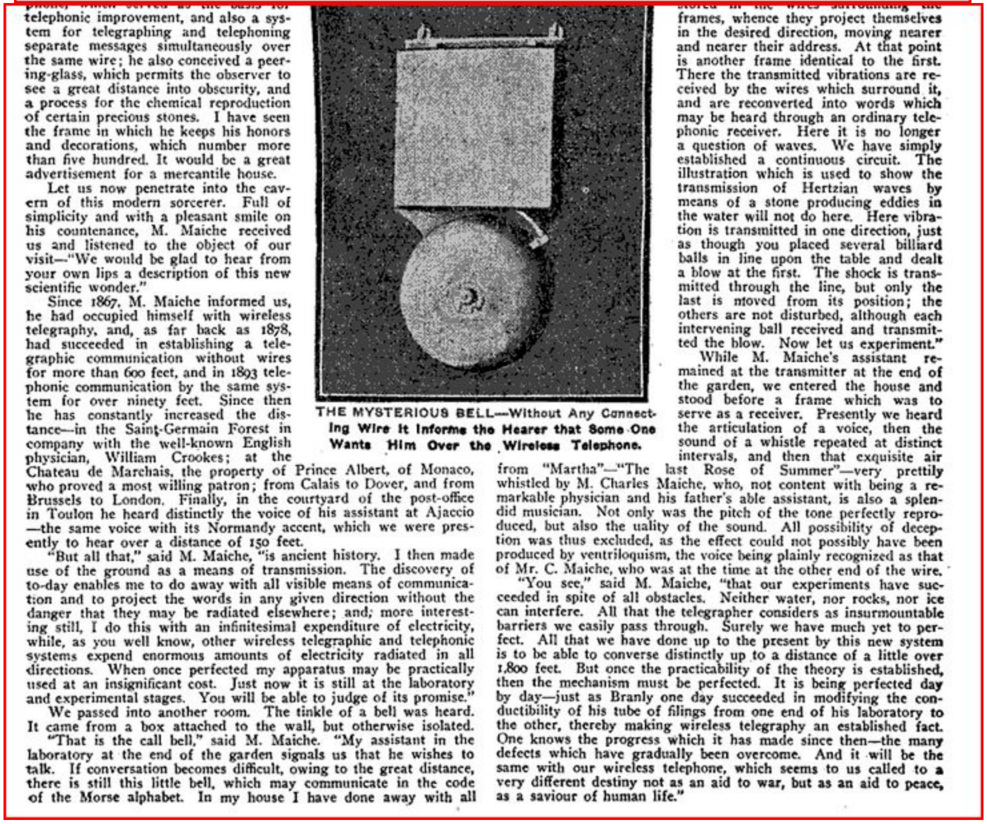
Aerial Message Projected Only in the Desired Direction; Words Are Inaudible Elsewhere

It is related of Gambetta, the famous French statesman, that he was wont to chide M. Thiers, his equally famous colleague, for the short-sightedness which led the latter to declare, when the locomotive was invented: "That will never move." But Gambetta himself was not less short-sighted. When Professor Bell, in 1867, invented the telephone, a modest French physician, Louis Maiche, went to Gambetta and, full of enthusiasm, begged him to interest himself in the matter. His hearer burst out laughing and interrupted him with: "My poor Maiche! What the deuce do you want to do with your plaything? It's good to amuse children." Gambetta and Thiers are long since dead, but Dr. Maiche, undeterred by the skepticism of men supposed to be wise beyond most men, has kept up his interest in the "plaything," and has now invented a wireless telephone which promises to make a revolution in even the perfected form of that "plaything." Recalling the interview with Gambetta, a French correspondent thus describes the invention:

Maiche, even then, had been honored as an inventor, already being known by his galvanic pile for the depolarization of the atmosphere, the model of which may now be seen at the Conservatory of Arts and Trades. Politicians, however, belong, for the most part, to that class which does not keep abreast of the science of the day. When I remember the life we led our professors of physics and mathematics I am quite willing to excuse the memory of Gambetta.

Later on Maiche invented the microphone, which served as the basis for telephonic improvement, and also a system for telegraphing and telephoning separate messages simultaneously over the same wire; he also conceived a peering-glass, which permits the observer to see a great distance into obscurity, and a process for the chemical reproduction of certain precious stones. I have seen the frame in which he keeps his honors and decorations, which number more than five hundred. It would be a great advertisement for a mercantile house.

Let us now penetrate into the cavern of this modern sorcerer. Full of simplicity and with a pleasant smile on his countenance, M. Maiche received us and listened to the object of our



telephonic improvement, and also a system for telegraphing and telephoning separate messages simultaneously over the same wire; he also conceived a peering-glass, which permits the observer to see a great distance into obscurity, and a process for the chemical reproduction of certain precious stones. I have seen the frame in which he keeps his honors and decorations, which number more than five hundred. It would be a great advertisement for a mercantile house.

Let us now penetrate into the cavern of this modern sorcerer. Full of simplicity and with a pleasant smile on his countenance, M. Maiche received us and listened to the object of our

visit—"We would be glad to hear from your own lips a description of this new scientific wonder."

Since 1867, M. Maiche informed us, he had occupied himself with wireless telegraphy, and, as far back as 1878, had succeeded in establishing a telegraphic communication without wires for more than 600 feet, and in 1893 telephonic communication by the same system for over ninety feet. Since then he has constantly increased the distance—in the Saint-Germain Forest in company with the well-known English physician, William Crookes; at the Chateau de Marchais, the property of Prince Albert, of Monaco, who proved a most willing patron; from Calais to Dover, and from Brussels to London. Finally, in the courtyard of the post-office in Toulon he heard distinctly the voice of his assistant at Ajaccio—the same voice with its Normandy accent, which we were presently to hear over a distance of 150 feet.

"But all that," said M. Maiche, "is ancient history. I then made use of the ground as a means of transmission. The discovery of to-day enables me to do away with all visible means of communication and to project the words in any given direction without the danger that they may be radiated elsewhere; and, more interesting still, I do this with an infinitesimal expenditure of electricity, while, as you well know, other wireless telegraphic and telephonic systems expend enormous amounts of electricity radiated in all directions. When once perfected my apparatus may be practically used at an insignificant cost. Just now it is still at the laboratory and experimental stages. You will be able to judge of its promise."

We passed into another room. The tinkle of a bell was heard. It came from a box attached to the wall, but otherwise isolated.

"That is the call bell," said M. Maiche. "My assistant in the laboratory at the end of the garden signals us that he wishes to talk. If conversation becomes difficult, owing to the great distance, there is still this little bell, which may communicate in the code of the Morse alphabet. In my house I have done away with all conducting wires. When you arrived here you rang the bell without a wire. When I call up my cook I do so without wire. A simple voltaic pile resounds to every vibration and without failure. But now come and hear my apparatus in action."

We found ourselves in the garden before a table on which were placed a small voltaic pile, an ordinary telephonic microphone, and a mysterious box not unlike that attached to telephones. At the side of the table was a large frame, about six feet square, similar to those used by artists for their canvases.

"In order to render my explanations more clear," said M. Maiche, "I will take you first to the post of the transmitter and then to the post of the receiver, although, in actual practice, the same post performs both services. This mysterious box which has aroused your curiosity is the nest of my invention. It is my special converter, composed of an electric reel, the wires of which are disposed in a peculiar manner which I may not reveal. When this converter is in action it changes ordinary electricity into vibrations, which are transmitted in straight lines to the post of the receiver. The two ends of this converter are attached to the frame, on the periphery of which is a groove, in which are buried two series of wires. One serves as a transmitter, the other as a receiver."

"And?"

"And that is all. The words which you confide to the microphone pass into the converter, awake corresponding vibrations which are stored in the wires surrounding the frames, whence they project themselves in the desired direction, moving nearer and nearer their address. At that point is another frame identical to the first. There the transmitted vibrations are received by the wires which surround it, and are reconverted into words which may be heard through an ordinary telephonic receiver. Here it is no longer a question of waves. We have simply established a continuous circuit. The illustration which is used to show the transmission of Hertzian waves by means of a stone producing eddies in the water will not do here. Here vibration is transmitted in one direction, just as though you placed several billiard

frames, whence they project themselves in the desired direction, moving nearer and nearer their address. At that point is another frame identical to the first. There the transmitted vibrations are received by the wires which surround it, and are reconverted into words which may be heard through an ordinary telephonic receiver. Here it is no longer a question of waves. We have simply established a continuous circuit. The illustration which is used to show the transmission of Hertzian waves by means of a stone producing eddies in the water will not do here. Here vibration is transmitted in one direction, just as though you placed several billiard

balls in line upon the table and dealt a blow at the first. The shock is transmitted through the line, but only the last is moved from its position; the others are not disturbed, although each intervening ball received and transmitted the blow. Now let us experiment."

While M. Maiche's assistant remained at the transmitter at the end of the garden, we entered the house and stood before a frame which was to serve as a receiver. Presently we heard the articulation of a voice, then the sound of a whistle repeated at distinct intervals, and then that exquisite air from "Martha"—"The last Rose of Summer"—very prettily whistled by M. Charles Maiche, who, not content with being a remarkable physician and his father's able assistant, is also a splendid musician. Not only was the pitch of the tone perfectly reproduced, but also the uality of the sound. All possibility of deception was thus excluded, as the effect could not possibly have been produced by ventriloquism, the voice being plainly recognized as that of Mr. C. Maiche, who was at the time at the other end of the wire.

"You see," said M. Maiche, "that our experiments have succeeded in spite of all obstacles. Neither water, nor rocks, nor ice can interfere. All that the telegrapher considers as insurmountable barriers we easily pass through. Surely we have much yet to perfect. All that we have done up to the present by this new system is to be able to converse distinctly up to a distance of a little over 1,800 feet. But once the practicability of the theory is established, then the mechanism must be perfected. It is being perfected day by day—just as Branly one day succeeded in modifying the conductibility of his tube of filings from one end of his laboratory to the other, thereby making wireless telegraphy an established fact. One knows the progress which it has made since then—the many defects which have gradually been overcome. And it will be the same with our wireless telephone, which seems to us called to a very different destiny not as an aid to war, but as an aid to peace, as a saviour of human life."

THE MYSTERIOUS BELL—Without Any Connecting Wire It Informs the Hearer that Some One Wants Him Over the Wireless Telephone.

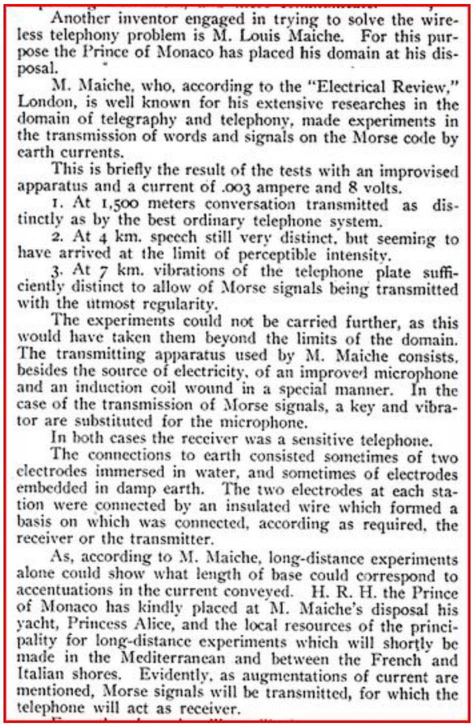
Telephony, Volumes 3-4



Another inventor engaged in trying to solve the wireless telephony problem is M. Louis Maiche. For this purpose the Prince of Monaco has placed his domain at his disposal.

M. Maiche, who, according to the "Electrical Review," London, is well known for his extensive researches in the domain of telegraphy and telephony, made experiments in the transmission of words and signals on the Morse code by earth currents.

This is briefly the result of the tests with an improvised apparatus and a current of .003 ampere and 8 volts.

1. At 1,500 meters conversation transmitted as distinctly as by the best ordinary telephone system.

2. At 4 km. speech still very distinct, but seeming to have arrived at the limit of perceptible intensity.

3. At 7 km. vibrations of the telephone plate sufficiently distinct to allow of Morse signals being transmitted with the utmost regularity.

The experiments could not be carried further, as this would have taken them beyond the limits of the domain. The transmitting apparatus used by M. Maiche consists, besides the source of electricity, of an improved microphone and an induction coil wound in a special manner. In the case of the transmission of Morse signals, a key and vibrator are substituted for the microphone.

In both cases the receiver was a sensitive telephone.

The connections to earth consisted sometimes of two electrodes immersed in water, and sometimes of electrodes embedded in damp earth. The two electrodes at each station were connected by an insulated wire which formed a basis on which was connected, according as required, the receiver or the transmitter.

As, according to M. Maiche, long-distance experiments alone could show what length of base could correspond to accentuations in the current conveyed. H. R. H. the Prince of Monaco has kindly placed at M. Maiche's disposal his yacht, Princess Alice, and the local resources of the principality for long-distance experiments which will shortly be made in the Mediterranean and between the French and Italian shores. Evidently, as augmentations of current are mentioned, Morse signals will be transmitted, for which the telephone will act as receiver.

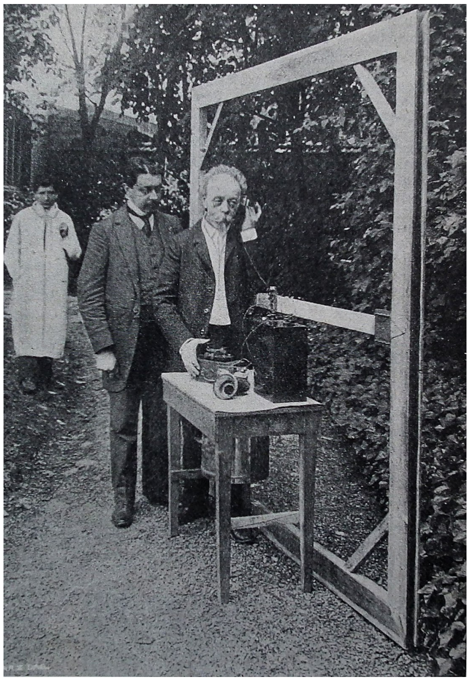
The world's first "mobile" phone (in 1906)

French inventor Louis Maiche and his wireless phone, arguably also the world's first mobile phone.
Image published in the Swedish weekly Hvar 8 Dag in September 1906 (Click to enlarge)



"M. Louis Maiche is the inventor of the wireless telephone and, like many scientists, is not so famous as he ought to be".

That is how an article in the Auckland Star on March 6, 1907, introduced the French inventor Louis Maiche, who also could be called the inventor of a mobile phone.

In the article M. Maiche describes how it all began:

"My first trials took place in 1867, but they were concerned more with wireless telegraphy, and it was not until 1893 that I exchanged a conversation through a wireless telephone at a distance of 30 yards."

Two months earlier, the New York Times had also published an article on M. Maiche and his wireless telephone invention. In the article the inventor refers to his successful experiments with telegraphy and then describes his work with the wireless telephone:

"I then made use of the ground as a means of transmission. The discovery of today enables me to do away with all visible means of communication and to project the words in any given direction without the danger that they may be radiated elsewhere; and, more interesting still, I do this with an infinitesimal expenditure of electricity, while, as you well know, other wireless telegraphic and telephone systems expend enormous amounts of electricity radiated in all directions."

"When once perfected my apparatus may be practically used at an insignificant cost. Just now it is still at the laboratory and experimental stages."

"You see", said M. Maiche,"that our experiments have succeeded in spite of all obstacles. Neither the water, nor rocks, nor ice can interfere. All that the telegrapher considers as insurmountable barriers we easily pass through. Surely we have much to perfect! All that we have done up to the present is to be able to converse distinctly up to a distance of a little over 1,800 feet. But once the practicality of the theory is established, then the mechanism must be perfected."

"It is being perfected day by day - just as Branly one day succeeded in modifying the conductibility of his tube fillings from one end of his laboratory to the other, thereby making wireless telegraphy an established fact. And it will the same with our wireless telephone,which seems to us called to a very different destiny, not as aid to war, but as an aid to peace, as a savior of human life."

In the Auckland Star article M. Maiche gives some examples of the future use of his wireless telephone:

"Imagine two steamers steering through a fog. With my little apparatus the captain can tell the direction the other ship is taking. In case of an accident to a submarine my apparatus would enable the crew in danger to communicate with the convoying tug without fearing the breaking of a line as in the case of a telephone buoy. Miners entombed after a disaster like that at Courrieres could communicate with the rescue party. Two army corps making a night attack could keep in constant touch without risk of interruption. The ordinary citizen could have it in his drawing room, and would no longer be dependent upon the vagaries of the telephone exchange."

Both articles also include some technical descriptions of the use of M. Maiche's new wireless phone. It is possible that the French inventor's theories were not as successful as he himself thought. Otherwise it is difficult to understand why this page (in French) is the only one with information about him that I have been able to locate. Still, his concept of wireless (and mobile) telephony should merit him a place in the hall of fame of modern communication technology .

Nouveau mode de transmission et de réception sans fil des signaux électriques
FR335990

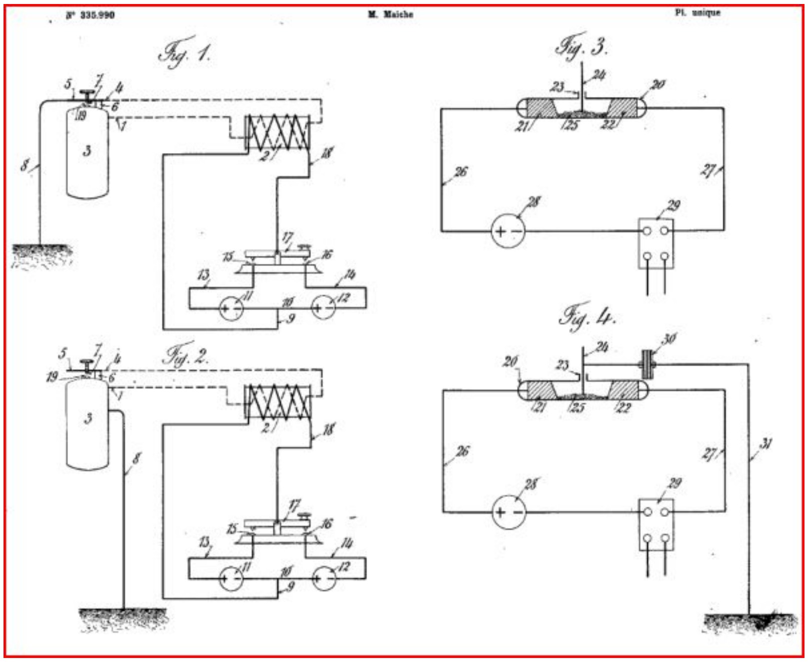
1904-02-22

The object of the present invention is a new method of transmitting and receiving wireless electrical signals. The essential means on which is based the system is the production transmits position and uses the position receiver electricity manifested in a new form which may be referred to as "electrostatic vibration" and is obtained as will be explained further by modification of a spark inductor. One of distinctive characters of this new manifestation of electricity is that it can be transmitted in space without the aid antennas and ground at all distances, and, in the same form as sound, light and heat, that is to say without poles.

The inductor being communicated c with a power source, a battery, for example, and a special switch which will be described below, each interruption is to be born in the armature current giving a spark, and it is the latter that is transform an "electrostatic vibration." The armature out of the coil wire after the last winding outside, is for this purpose connected to a large metal surface which can be exposed to air. This surface may be constituted either by c a hollow or solid cylinder or by one or more sheets of iron, copper or any other metal usual more or less thick. The surface is preferably rounded at the corners or packed with a border all around to remove spikes, as in the conductive electrostatic machines. It should be about one square meter per watt of the current flowing in the inductor. The other end of the armature is connected to an adjusting screw of which the tip k of platinum or gold is next to a button, also in a gold or platinum, carried on the large surface.

FIGS. 1 and 2 of the accompanying drawings show two provisions which may be 5 h adopted for the preparation of the transmitter station.

FIGS. 3 and k show two provisions and receiver.



One end of the armature wire of the coil -j is connected to the cylinder 3 rounded at its ends, and the end k of the wire is connected to plate 5 mounted on the insulating support 6 which is fixed to the cylinder 3 . The plate 5 is traversed by a setscrew 55 provided beyond tip 7 made of gold or platinum. The end of the induced wire k is that by which begins rolling on a bobbin. Wire 8 communicates with the earth or the plate 5 (Fig. I) is the cylinder 3 (Fig. A).

Improvements in and relating to Electric Transformers.
GB190727157

1908-10-29

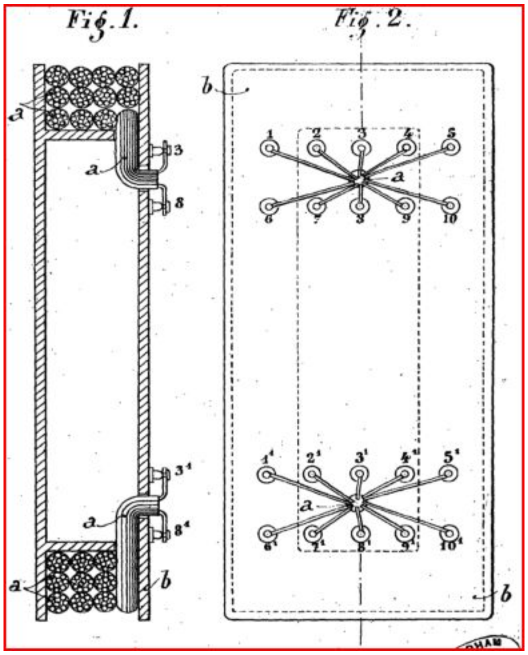
Comprises a large number of windings wound in the form of a cable a on a coreless frame b, and led out to terminals 1 ... 10 and, adapted to be connected in quantity or tension by means of a commutator so that three or more independent circuits may be made.

COMPLETE SPECIFICATION.

The present invention relates to electric transformers of the class described by Specifications Nos. N;821901 (Amberg), z1854 (Swinburne), and 4/I83 (Clerc) and it particularly concerns the arrangement of the windings.

The invention is represented in the accompanying drawings;-

Figs. 1 and 2, show a section and a front view respectively of the improved transformer.



The transformer which has no magnetic core, is merely constituted by a convenient number of insulated wires, 10 for example, which are united to form a cable a which is wound around a frame b. The ends of the cable project through two holes of the frame and the ends of each wire are joined to terminals 1 to 10 and 11 to 101 respectively. In the drawings are shown 20 terminals, the first ten of which correspond to the beginnings of the 10 wires, and the other ten correspond to the ends of the same wires.

Thus, a winding of a certain number of identical wires is obtained which are all wound parallel and simultaneously and which may be connected by means of a commutator so as to form groups to 'be varied according to requirement; so that there are thus constituted three or more circuits which are entirely independent the one of the other and the length of which can be varied at will.

By conveniently joining the free ends of some of the wires, a primary winding of weak resistance is obtained with the wires of same joined for quantity, while one or more of the secondary windings are joined for tension, thus providing any required resistance.

The construction of the transformer by means of a great number of separate wires offers numerous advantages amongst which are the facility of connecting the separate wires at will to constitute the circuits; the arrangement enabling a supplementary circuit to be branched off at any point of the said circuits; and the reciprocal independence of these circuits with large number.

Improvements in and relating to Electric Transformers.
GB190721535

1908-05-28

Transformers for telegraphy and wireless telegraphy are made without a magnetic core, and of little depth but of large diameter. They have the primary winding e enclosed within the secondary winding c, g, but separated therefrom by insulation d, f. The windings may be formed in sections, and coupled up in any order by means of a commutator.

COMPLETE SPECIFICATION.

This invention relates to electric transformers the construction of which is improved so that currents of induction of very short periodicity are obtained.

The currents, the duration of which is extremely short, possess special properties which are particularly useful when applied in telegraphy and in wireless telephony.

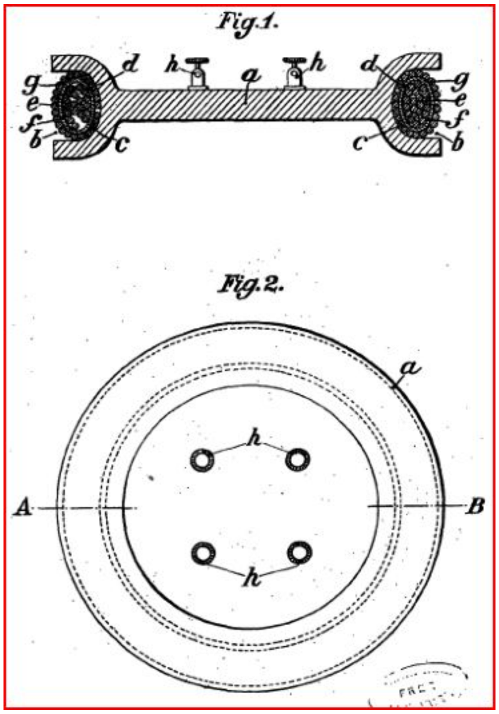
Transformers without magnetic core and with the secondary winding wound around the primary, or with the primary winding enclosed within insulating material round wh,ich is wound the secondary winding so that the whole forms a cable, have been provided, and my invention is limited to the form and construction of the transformer as hereinafter set forth.

My improved electric transformer contains its primary wire within a cable of the secondary wires in the form of a single coil of little thickness but of very large dia,meter, said coil or cable being applied to a ring-shaped transformer body.

The accompanying drawing shows my improved electric transformer.

Fig. 1 is a section on line A-B of Fig. 2 and

Fig. 2 is a plan of the ring-shaped transformer.



As will be seen from the drawings, the transformer a is of comparatively large diameter which may be several meters. In the drawing the transformer is represented of circular cross-section, it could however be of square or other cross-section. This transformer is very short because all the wires of the winding are located on its periphery in an appropriate hollow or groove b. For manufacturing the trans-former I place around the rim of this kind of wheel or dial: a, a first layer of secondary wire which is covered by a suitable insulator d and upon this insulator the primary wire e is wound which is covered by another layer of insulating material f. The two insulating layers d and f are connected in such a manner that the primary wires e are well insulated, and the coil is then finished by applying an outer winding of secondary wire g, the latter surrounding the primary in such a manner as to form a cable. In this manner a ring of large diameter is obtained which is composed of the secondary wires c, g which enclose a core of suitably insulated and wholly surrounded primary wires e and which ring is applied to a ring-shaped transformer-body having a peripheral groove of suitable cross-section.

The apparatus comprises four terminals h, two of which serve for fixing the ends of the secondary wires, the other two serving for fixing the ends of the primary winding.
There could be arranged several independent cables or rings in each of which the secondary wires entirely surround the primary wires and in such case each of the terminals would be replaced by a multiple commutator permitting to join up the different secondary wires as well as the different primary wires either for tension or for quantity according to the effect to be obtained.

Improvements in connection with Wireless Telegraphy and Telephony.
GB190721252

1907-11-21

The transmitting and receiving circuits at one station for an inductive system of telephony or telegraphy are arranged as shown. A coil a, consisting of a few turns of thick wire, is used alone in transmitting, but is connected in series with a coil b, consisting of a large number of turns of fine wire, for receiving; the circuit of the coil b is broken automatically, during transmission, by means of a Morse key c. The circuit of the coil a includes a battery n and a microphone o for telephony, or an interrupter for telegraphy, and the coil b is connected with a telephone h.

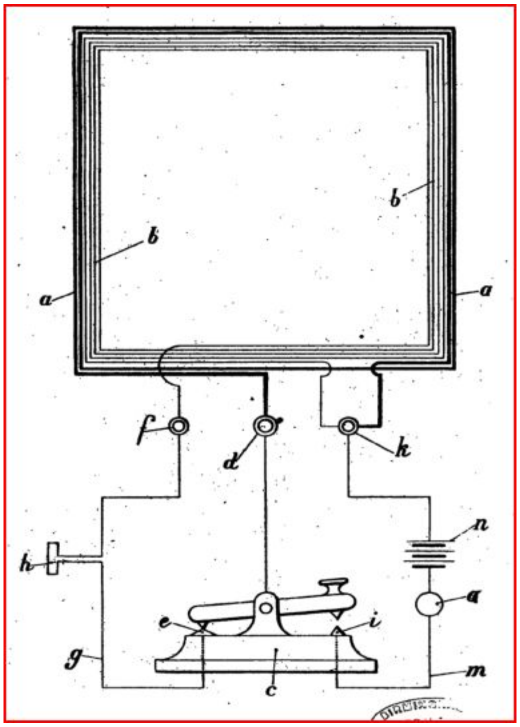
There are known systems for telegraphy and telephony without connecting wires which utilise, instead of Hertzian waves, the phenomena of distant induction by means of electric vibrations of very short duration, but great amplitude. With such systems, one and the same winding is used fur sending and for receiving; for sending it is placed in circuit with a source of electricity (battery, accumulator, etc.) and with a microphone or an interrupter destined to produce the vibrations in question. The same winding is placed in circuit with a .receiving telephone .for receiving the currents which arc induced at a. distance from the sending winding of the other station.

It is obvious that this single coil cannot equally well serve for the sending as for the receiving. To transmit well it ought to be made from thick and short wire, whilst for receiving well it ought to be of long and thin wire.

It would evidently be the simplest to provide each station with two different coils of which one serves as transmitter and the other as receiver, but lucre is another difficulty to be considered; for receiving, the long and thin coil has to be closed by the telephone and in that condition it would absorb nearly all the energy which ought to be sent out by the transmitter.

The present invention rotates to a special method of mounting the parts constituting a station in order to overcome the above mentioned difficulty; besides, the special method of mounting permits to join the two coils one behind the other for receiving whereby the receiving power of the station is considerably increased.

The accompanying drawing represents diagrammatically a station according to the present Invention.



a is the inductor wire which serves fur transmitting; this wire is thick and relatively short. b is the induced winding for receiving the induced vibrations from the inductor winding of the transmitting station; this winding consists of thin wire of considerable length. c is a. Morse-manipulator the lever of which is connected through the contact let with one end of wire a, its connector e is through the contact f connected with one of the ends of wire; the wire g which connects the contact f with wire b comprises the telephonic receiver h ;the other connector i of the Morse apparatus is connected through terminal with the free ends of the two wires a and b which are joined at this point. The connecting wire m which serves for this purpose, comprises the battery n and the microphone o.

It is easily' understood that in the inoperative position of the Morse key (as represented in the drawings) the two coils and b form one circuit closed on the telephone h. This position is the receiving position. For transmitting, the key is depressed and brought in contact with the connector whereby the coil b is opened whilst the coil a is closed on the microphone and the battery.

It is to be understood, that the station described serves for the transmission of sounds. For the transmission of telegraphic signals, the microphone o is replaced by a suitable interruptor-vibrator and the apparatus is operated through the Morse key as usual.

Improvements in and relating to Inductive Telegraphy and Telephony.
GB190712529

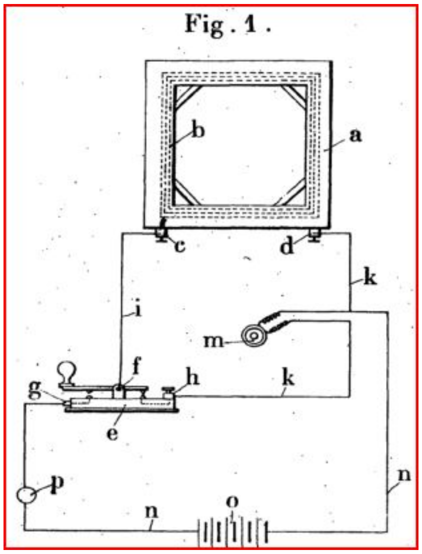
1908-03-12

In a system of telegraphy or telephony by magnetic induction, the coils are placed vertically and the same coil is used for transmitting and receiving. The coil b is wound on a frame a of any suitable shape, which may be lined with iron. One terminal of the coil b is connected to a key f, one contact of which is connected through a microphone p and battery o to the other terminal d of the coil. A telephone m is connected across the terminals of the coil through another contact of the key f, and its circuit is normally completed for receiving telephonic or telegraphic messages. Telegraphy is effected by manipulating the kev f to complete the circuit of battery o ; to telephone, the key is depressed and the microphone p is utilized. A high-frequency alternator may be used instead of the battery o, and a screen composed of sheets of paper soaked in paraffin, varnish, or glue may be placed behind the frame.

The present invention relates to improvements in that class of magnetic induction telegraphy and telephony in which transmission is effected between similar coils of wire at the receiving and transmitting stations. The invention is characterized by the fact that senders and receivers.are reversible, the member for transmitting the waves being the, same as the member which receives the waves.

In the drawing, a diagram of a station according to the present system is represented.

Fig. 1.



The transmitter and receiver for the electric waves consists of a. wooden frame (a) of fairly large dimensions; for example 4 meters square for a distance of 20 kilometers. In the drawing the frame is shown as being square but it may be of any other geometric shape having as center a.rectangle a lozenge, a circle, etc. The wall of the frame is provided with a groove (b) in which an insulated conducting wire is placed which is connected with the terminals (c) and (d). This wire is wound a. varying number of times around the frame so that it is of sufficient length according to the power of transmission required of the apparatus.

The frame (a) must be of sufficiently large dimensions to prevent the currents generated in opposite directions in the sides of the frame from tending to neutralise each other.

Each station comprises besides a Morse manipulator (e), the commutator of which is connected with one of the terminals (c) of frame (a) through the wire, its terminals (r) and (h) being connected with the other terminal (d) of frame (a).

An ordinary telephonic receiver (m) is inserted in, the circuit (k) which leads from the terminal (h.) of the manipulator to the frame, and in the other circuit (n), connecting the terminal (g) of the manipulator with. the frame, a battery (o) is inserted near the frame and , microphone (p) is inserted near the manipulator.

When the manipulator (c) is at rest (position shown in the drawing) the station is ready to receive the transmissions, the electric circuit (a, c, i, f, m, k, d, a) enclosing the frame and the telephone -being closed. One has only to hold the telephone to the ear to perceive all the currents which a.re induced in the frame (a).

The telephone (m) is put out of circuit when the commutator (f) is pressed down, whilst t.he circuit will be closed upon the frame (a.) and battery (o). The station has thus become 11 sender, the battery sending variable currents into the frame according to the nature of the transmission to be effected. To telegraph according to the Morse alphabet one manipulates the commutator (f) in the usual manner, the telephone (m) of the other station permitting to distinctly perceive the dots and dashes. The operator simply gives one contact for the dot and two contacts following in quick succession for a dash. In this case the microphone (p) is superfluous but it does not disturb. When however one wants to telephone, the contact (g) has to be kept closed and one speaks in front of or into the microphone (p); the telephone (in.) of the other station will reproduce the sounds.

The source of electricity (o) can be a battery or an electro-magnetic generator giving alternating currents of high frequency. The currents which are thus sent into the frame (a) of the sender station have no appreciable effect upon the telegraphic receivers which could be provided at this station; they even do not influence the magnet needle owing to their **illst,nntfmeousness.**

To establish the communication between two stations the two frames (a) have to be placed in parallel planes, perpendicular to the line which would connect their centers, which can be effected through various means. The action (if the one of the frames on the other is effected through any obstacles whatsoever, no earth connection or air connection being necessary.

The reciprocal action of the frames can be increased through lining the bottom of groove (b) for its entire length with soft sheet iron, the lining being continuous or interrupted. The frame will thus become a kind of electro-magnet, the proportion of which are just the reverse of those generally used.

To communicate at very great distances several frames (n,) are joined up, the wires being joined up in series or for tension.

The efficiency can be considerably increased and the direction of transmission localised in avoiding dispersion at the sides or behind the frame, by means of a thick screen composed of superposed sheets of paper soaked in paraffn ; the paper could also be impregnated with varnish, glue or any other equivalent material.

Improvements in and relating to Telegraphic and Telephonic Systems.
GB190126600

1902-11-06

Relates to the arrangements of circuits in telegraph and telephone systems. In Fig. 1, a microphone b is shown in a main line a, and at the receiving-station is connected to the middle of a split battery f, g, two receivers l, m being connected between battery and earth. When induction coils are employed, two separate primaries take the place of the receivers in the Figure, and the receiver employed is placed in a common secondary. In another modification, the transmitter is bridged across two parallel closed circuits, including primaries and batteries, the secondary forming the line circuit.

This invention relates to telegraphic and telephonic systems and has for its object certain improvements hereinafter more particularly referred to and finally pointed out in the claims.

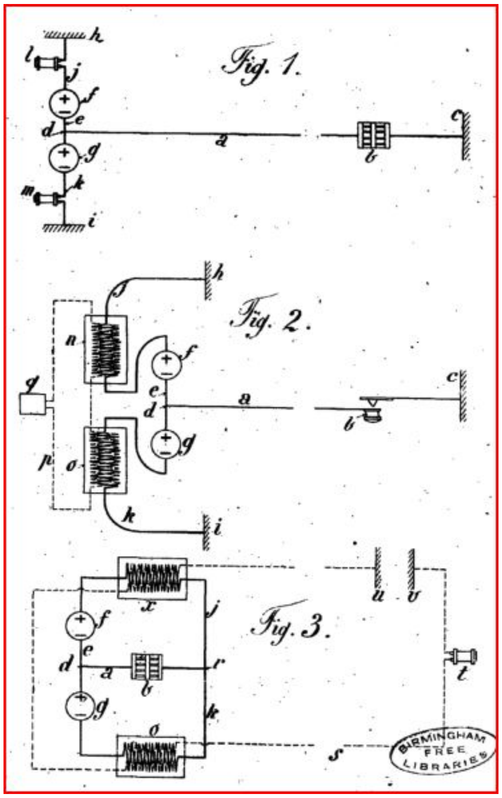
As is well known, in order to prevent over-heating of' the receiving and transmitting apparatus in telephonic or telegraphic installations it is necessary to prevent very strong current passing over them. It may however, in certain cases, be necessary to provide currents of varying energy within rather large limits, and this invention has for its object to provide a simple device which will permit currents of any force being passed through telegraphic and telephonic apparatus without the slightest risk of deterioration to such apparatus.

In order that my invention may be readily understood and carried into effect I will now proceed to describe the same fully with reference to the accompanying drawings wherein are shewn diagrammatically several methods of carrying my. invention into practice.

In the drawings :

Figure 1 shows the principle of my improved arrangement, and

Figures 2. and 3 are modified arrangements.



My improved system consists essentially of a line a of any convenient length in which is interpolated a microphone b or other appropriate transmitting apparatus. One end of this line is grounded at c and the other end is connected at d to.a wire e adapted to place into communication the opposite poles of the two sources of electricity of equal power, which for greater clearness sake I have represented as two single batteries f and g. These two batteries are respectively connected to earth at h and i. In the earth wires j and k are interpolated telegraphic or telephonic receivers l, m, of any convenient construction. In the example shown in the drawing the receivers and m are indicated as being telephonic receivers.

Having thus described the general arrangement of the system I will now explain the function of the various apparatus of the system.

Presuming that the wire a is non-existent and that the communication of the battery f and g with the earth has been established, a current passes from the positive pole of the battery f to earth through the wire then back .through the wire k, battery 9 and finally through the wire e to the negative pole of the battery f. Thus a closed circuit is established. Admitting now the wire a to be connected to the wire e at d and the transmitter b operated, the single current generated in the previous case will be replaced, by two currents which circulate in the same direction.

One of these currents starts from the positive pole of the battery f through the wire through earth from h to c through the transmitter b, wire a and wire e to the negative pole of the battery f.

The other current starts from the positive pole of the battery 9 through the 'wires e and a, the transmitter b, through earth from c to i and wire k to the negative pole of the battery g.

It will thus be seen that the wire a and transmitter b are simultaneously traversed by two equal currents in inverse directions.

In Figure 2 I have shown a telegraphic transmitter or key b but the general arrangement of the system is the the same as that previously described with the exception that the wires j and k form the primary conductors of the transformers n and o. The secondary conductor p, which is common to both transformers, leads,to the receiving apparatus q, for example a telegraphic receiving instrument.

Each contact ejected with the key b produces, as before explained a double derivation acting by subtraction of intensity upon the two transformers n and o, produces an induced current which is reproduced in totality in the receiving apparatus q. In the case of telephonic transmission the key must be replaced by a microphone as shown in Figure 1, while further the receiver q would also be a telephonic receiver.

By extending the same principle I can, as indicated in Figure 3, replace the two earth wires by two conductors and k joined together at r after having traversed the transformers x and o. The induced current may then be conveyed to the receiving instrument t over two lines, or as in the previous example over a line s and two earth connections u and v, placed more or less apart from each other.

It will be noticed that the microphone b forms part of the neutral conductors.

It acts exactly as in Figure 1. The differences of resistance produced by its vibrations influence the two coils x and o, and it is easy to understand that, whatsoever may be the intensity of the two electric sources f and g, the microphone is never exposed to the risk of becoming overheated for the reason that it is traversed by two equal currents in opposite directions.

It will thus be understood that the transmissions will be rendered perceptible in the receivers through the differences of intensity of the electric current; the differences being due to the differences of resistance of the neutral conductor which, in receiving two equal currents in opposite directions, is not much affected itself.

Improvements relating to the Transmission of Telegraphic and Telephonic Signals.
GB190117711

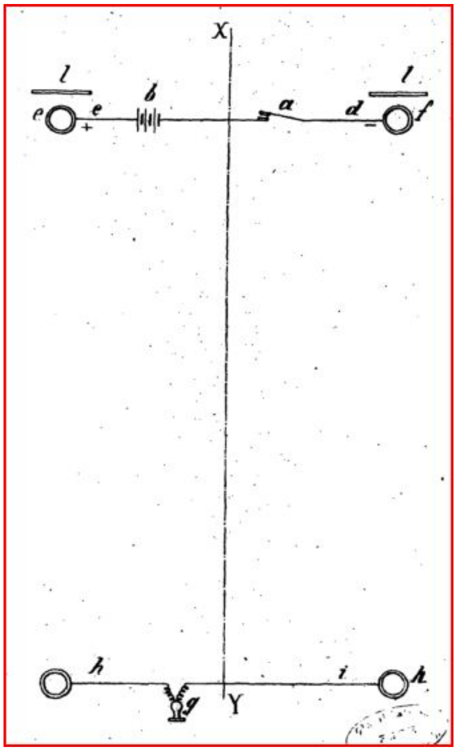
1901-02-19

The local circuits at each station are doubly earthed at e, f, j, k symmetrically about a straight line joining the stations. The earths may be formed of porous pots containing water in which the ends of the conductors are immersed, or deep ditches filled with gas coke may be employed. Insulating screens may be placed in deep ditches dug behind the earths.

This invention relates to an improved method of transmitting electrical telegraphic and telephonic signals from one point to another without the employment of wires connecting the two points.

In my improved system of transmission, the two poles of the transmitting station are put to earth and the two conductors, upon which the receiving apparatus is mounted are also both put to earth; the signals emitted by the transmitting apparatus are transmitted to the receiving station through the earth alone.

In order that my invention may be readily and clearly understood, I have represented in the accompanying drawing, by way of example only, a diagrammatic view of my device as a whole.



As shewn in the drawing, the transmitting station comprises a transmitter a one of the terminals of which is electrically connected to one of the poles of a source of electricity b whilst the other pole communicates with the earth; the second pole of the source of electricity is also run to earth and with this object the two conductors c d terminate in two porous pots e f embedded in the ground and filled with water.

The receiving station comprises a receiver 9 such as a telephone for example, the conductors h i which are put to earth by the intermediary of two porous pots j k similar to those of the transmitting station.

The porous pots of the receiving station should be arranged upon a line parallel with that which joins the two porous pots of the transmitting station, and they should be equidistant from an axis passing through the middle point of this line and at right angles to said axis.

The porous pots may advantageously be replaced by deep ditches sunk down to the humid earth, filled with gas coal or coke and containing at their centre a plate of carbon which is a good conductor, to which the transmission and receiving wires respectively are attached.

When contact is established by manipulation the transmitter a, the electric circuit passing through the source of electricity b, the conductor c, the porous pot e earth-connected to the other porous pot f the conductor d and the transmitter a, is closed. The current thus produced causes a change of condition in the ground ; all around the porous pots electric radiation is produced, the polarity of which is that of the corresponding conductor; its density decreases in proportion as it is further removed from the point of departure. This radiation is infinite with respect to space if nothing obstructs its passage.

The radiation extends so much the further according as the distance between the two porous pots of the transmitting station is greater.

These radiations, starting respectively from the porous pots e f thus create two zones one of which is positive and the other negative, the intersection of which constitutes % line absolutely neutral. It follows from this that the porous pots of the receiving station should be arranged upon either side of the neutral axis, because if these two earth connections were upon the same side they would both collect fluid of the same polarity, and in these conditions the receiver would not be traversed by any current.

In order to collect the maximum of current at the receiving station, the two porous receiving pots should be as nearly as possible equidistant from the neutral axis, as if one of the two porous pots is nearer than the other, the difference of separation of that which is the furthest removed is not only lost but is prejudical since it causes useless resistance without adding anything to the effect.

Experience has demonstrated that the disposition which furnishes the maximum of reception is that which consists in arranging the porous pots of the receiver at the same interval as separates the porous pots of the transmitting station.

In order to install my method of electrical transmission, it is first of all necessary to draw a straight line a y connecting the two stations and .then to produce upon each of these stations a line proceeding from this line x y at right angles, the said perpendicular lines being of equal length.

The transmitting and receiving appliances may be arranged at any convenient point on the conductor which connects the porous pots.

In order that the whole of the radiation emitted may be utilised at the receiving station, the propagation of this radiation is prevented (at the transmitting station upon the side opposite to that on which the receiving station is situated by burying in the ground an insulating screen l which may be of glass, tarred fabric, ebonite or the like, or by sinking a sufficiently deep ditch with or without an insulating screen.

Each time contact is made at the transmitter a, a sharp blow is audible at 'the receiving telephone g ; a second blow is heard when the circuit is broken.

It is obvious that there may be arranged both at the transmitting and receiving station transmitting and receiving appliances of the greatest possible sensibility, either for serving as relays for telegraphic purposes, or for directly receiving and recording the signals; for example an ink siphon mounted upon a galvanometric frame, or any other suitable device.

My method of transmission also permits of the transmission of speech; it is only necessary to replace the transmitter by an ordinary microphone interposed either directly upon the circuit, or arranged upon the primary of an induction coil, the secondary wire of which terminates at each extremity of the two porous pots.

It will of course be understood that in practice each station comprises both a transmitter and a receiver.

Improvements relating to the Transmission of Electric Currents
GB190108906

1901-04-30

Telegraph and telephone systems are arranged with the line-wire a connected to the center point of a battery c, c, the opposite poles of which are earthed and shunted by a normally closed circuit key g or microphone. The earth connections are made through non-polarizable cells f, f, containing, for example, two plates of copper immersed in copper-sulphate solution. The receiver is bridged between one earth and a switch h by which the transmitter is normally connected to line. The microphone may be inserted in the primary of an induction coil, the two secondaries of which oppose and are connected to the two earths and line. The two earth connections may be brought nearer together by the receiver and switch in the primary of the induction coil, so that this coil acts both to receive and transmit according to the position of the switch h. The microphone is arranged in the primary of a second induction coil.

This invention relates to improvements in the transmission of electric currents and is more particularly adapted for telegraph and telephone lines, whereby condensation in the cable is avoided, while at the same time "tapping" of the , line at any point thereof, for the purpose of ascertaining the purport of the message in transmission is rendered impossible.

My improved system of transmission comprises a single line wire between the two stations and branched at these two stations to the zero point of a circuit, the two extremities of which are connected to earth or the sea ; the current furnished at each station by a local source of electricity being sent through the circuit by means of any convenient transmitting apparatus, (such as a Morse key, microphone or the like) either direct or by induction.

Each station is furnished amongst other apparatus, with a receiving apparatus consisting of a key-instrument connected with the line-wire and permitting the current sent into the line from the transmitting station, to pass into a conductor leading direct to one of the wires running to earth and to which is connected the receiver proper.

In order to avoid the polarization of the earth-wires, each such wire is connected with a conductor leading to a copper or other metallic blade immersed in an impolarizable saline solution in which is disposed a second similar blade connected to earth or sea.

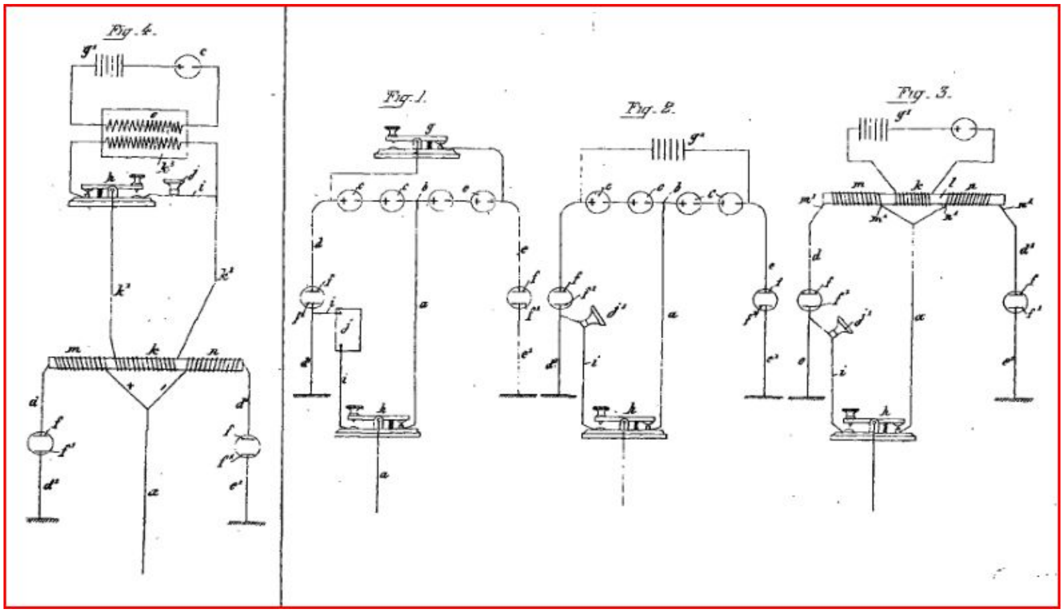
In the accompanying drawings :

Figure 1, is a diagram showing my improved system as applied to telegraphy

Figure 2, is a diagram showing the same applied to telephony.

Figure 3 shows the system of Figure 2 with induced current.'

Figure 4, shows a modified arrangement.



In all the figures the same letters of reference designate the same parts.

Referring to Figure 1 the two stations are connected by a single line-wire a, branched at the zero point b of the battery formed of the different elements c of which the end poles are connected to earth, or to sea, by a conductor d e lead- ing to a copper or other metallic plate f immersed in a liquid of good conductivity, such as for example a solution of a sulphate of copper, in which another copper plate f1 is placed connected to earth, or sea by a conductor d1 .

A transmitting apparatus g of any convenient construction, such as a Morse- key instrument, is connected with the two end poles of the battery in such a manner that in its position of rest it closes the circuit of the latter by establishing a short circuit so that no current passes, (or at most a very weak one) through the wire line a or through the earth-wires.

To send a current to the receiving station, the key 9 is depressed whereupon the short circuit is interrupted and the current is caused to pass simultaneously through the line-wire a and the earth-wires d d1 e e*. The line-wire is in reality traversed by two currents in opposite directions, so that it is in an apparently neutral state, and thus no interception of the messages can be effected for the, reason that if a receiver be interpolated, at any point of. the line, said receiver would receive two currents in opposite directions' which would neutralize each other.

Each station is furnished also with a receiving apparatus consisting of a commutator h connected with the line-wire a and permitting, when depressed, the current from the transmitter to pass into a wire i leading direct to one of the earth-wires (d1 for example) and in which is interpolated the receiving instrument j.

To receive signals sent from the transmitting station, it 'is necessary that the commutator lever h be kept depressed, so as to cause the current from the transmitting station to pass into the wire In connection with the receiving instrument.

'The connections may also be established in such a manner that when the commutator h is in its normal .position, it cuts the wire (and connects the wire with that part of the said wire which leads to the other station ; in this case for transmitting a signal it is necessary to depress the commutator lever h previously so as to re-establish the continuity of the line-wire and the operator then acts on the key-lever g as hereinbefore stated.

My arrangement is equally applicable to telephonic messages as will now be explained with reference to Figure 2, The transmitting instrument g is in this case replaced by a microphone g1 and the receiving instrument j is replaced by a telephone receiver j 1 the operation of the arrangement is exactly, the same as that above described.

The vibrations of the microphone cut the short circuit and the current from the local, source of electricity thereupon passes over the line-wire a and the earth-wires d d1 c el as previously stated.

The telephonic message is received in the same manner as before through the intervention of the commutator h which passes the current, sent from the transmitting station; to the telephonic receiving instrument jl.

The line-wire may also be operated by induction currents a3 is indicated at Figure 3.

The local circuit in which the transmitting apparatus (for instance, the microphone g1) is inserted comprises a primary winding k surrounding a central soft-iron core, or bundle of wires, l which is further provided with two secondary windings m m in opposite directions. The line wire a is connected to each of these secondary windings at the two extremities m1 n1 of opposite polarity and the opposite extremities ms p2 are connected with the earth-wires d d c set in the manner already explained.

When operating the transmitting apparatus or when speaking into the microphone 0 for example, induction currents are generated in the secondary windings m n and they then affect the receiving apparatus jl at the receiving station as already stated.

The primary winding and the two secondary windings may have the three wires wound in the same direction upon the soft iron core and the two extremities of the primary convolutions are connected with the local circuit in which is interpolated the transmitter while two extremities of opposite polarities of the secondary convolutions are connected to line and the two osiers to earth as previously explained.

In my improved transmitting arrangement the two earth wires at 'each station must be the more separated from each other the longer the distance is between the two stations so that the resistance of the earth between the said earth-wires will be sufficient to cause the single line-wire to be traversed by the greatest possible quantity of the current.

In order to reduce as far as possible the distance between the earth-wires the beginning of the single wire a and the wires rl rl' leading to earth are advantageously rm distance from the transmitting instrument and receiving instrument respectively at the telegraphic or telephonic station and thus permit the two earth connections of the two telegraphic or telephonic stations to be placed nearer each other.

The telegraphic or telephonic station is then divided and the transmitting instrument is connected with the magnet with its earth connections and line wire a ' by two conducting wires kl k2 connected with the ends of the convolutions k which generates induction currents in the secondary windings m n (Figure 4).

The current sent into the conducting wires k1 k2 and. passing through the convolutions k may itself be an induced current generated in the coil k3 when a current from the source of electricity c is passing through the. primary coil o through the action of the transmitting microphone gl for example.

In the case when' the distance of the telegraphic or .telephonic transmitting station from its earth-connections is not too excessive the current traversing the conductors k1 1.:2 instead of being an induction current may be furnished direct by the source of electricity of such station, and naturally the, transmitting instrument, (microphone or 'key), and the source of electricity are then placed direct in the circuit;1 k2.

An interrupter A interpositioned in the conductor kl permits of cutting the circuit in leading to the secondary coil k3 and of closing the circuit for the conductor i leading to the conductor k 2 in which is interpolated' the receiving instrument j.

Thus the coil k is either inductor or induction according to whether there is transmission or reception.

It is to be well understood that my system of transmission is entirely independent of the nature of the telegraphic or telephonic apparatus employed therewith, and that the source of electricity at the stations may be of any convenient kind, either derived from a battery, accumulators, dynamo, magneto-electric machine or the like.

COMPLETE SPECIFICATION.

This invention elates to improvements in the transmission of electric currents and is more particularly adapted for telegraph and telephone lines, whereby condensation in the cable is avoided, while at the same time "tapping" of the line at any, point thereof, for the purpose of ascertaining the purpose of the message in transmission is rendered impossible.

My improved system of transmission comprises a single line-wire between the two stations and branched at these two stations to the zero point of a circuit, the two extremities of which are connected to earth or the set; the current furnished at each station by a local source of electricity being sent through the circuit by means of any convenient transmitting apparatus, '(such as a Morse key .microphone or the like) either direct or by induction.

Each station is furnished, amongst other apparatus, with a receiving apparatus consisting of a key-instrument connected, with the line-wire and permitting the current sent into the line from the transmitting station, to pass into a conductor leading direct to one of the wires running to earth and to which is connected the receiver proper.

In order to avoid the polarization of the earth-wires, each such wire is connected with a conductor leading to a copper or other metallic blade immersed in an impolarizable saline solution in which is disposed a second similar blade connected to earth or sea..

In order that my invention may be clearly understood and readily carried into effect I will now proceed to describe the same more fully with reference to the drawings accompanying my Provisional Specification in which:.

Figure 1, is a diagram showing my improved system as applied to telegraphy.

Figure 2, is a diagram showing the same applied to telephony.

Figure 3 shows the system of Figure 2 with induced current.

Figure 4 shows a modified arrangement.

In all the figures the same letters of reference designate the same parts.

Referring to Figure 1 the two stations are connected by a single line-wire a branched at the zero point b of the battery formed of the different elements c of 'which 'the end poles are connected to earth, or to sea, by a conductor d e leading to a copper or other metallic plate f immersed in a liquid of good conductivity, such as for example a solution of sulphate of copper, in which another copper plate f1 is placed connected to earth, or sea by a. conductor d1 e1.

A transmitting apparatus q of any convenient construction, such as a Morse-key instrument, is connected with the two end poles of the battery in such a manner that in its position of rest it closes the circuit of the latter by establishing a short circuit so that no current passes, (or at most a very weak one) through the wire line a or through the earth-wires.

To send a current to the receiving station, the key g is depressed whereupon the short circuit is interrupted and the current is caused to pass simultaneously through the line-wire a and the earth-wires d d1 e el. The line wire is in reality traversed by two currents in opposite directions, so that it is in an apparently neutral state, and thus non interception of the messages can be effected for the reason that if a receiver be .interpolated at any point of the line, said receiver would receive two currents in opposite directions which would neutralize each other

Each station is furnished also with a receiving apparatus consisting of a commutator h connected with the line-wire a and permitting, when depressed. the current from the transmitter to pass into a wire i leading direct to one of the earth-wires (d1 for example) and in which is interpolated the receiving instrument j.

To receive signals sent from the transmitting station, it is necessary that the commutator lever h be kept depressed, so as to cause the current from the transmitting station to pass into the wire i in connection with the receiving instrument.

The connections may also be established in such a manner that when the commutator h is in its normal position, it cuts the wire' a and connects the wire i with that part of the said wire which leads to the other station; in this case for transmitting a signal it is necessary to depress the commutator lever h previously so as to re-establish the continuity of the line-wire and the operator then acts on the key-lever as hereinbefore stated.

My arrangement is equally applicable to telephonic messages as will now be explained with reference to Figure 2. The transmitting instrument g is in this case replaced by a microphone 1 and the receiving instrument j is replaced by a telephone receiver il the operation of the arrangement is exactly the same as that above described.

The vibrations of the microphone cut the short circuit and the current from the local source of electricity thereupon passes over the line-wire a and the earth-wires d d1e e1 as previously stated,

The telephonic message is received in the same manner as before through the intervention of the commutator h which passes the current sent from, the transmitting station to the telephonic receiving instrument j1.

The line wire may also be operated by induction currents as is indicated at Figure 3.

The local circuit in which the transmitting apparatus (for instance, the microphone g1). is inserted comprises a ,primary winding k surrounding a central soft iron core,, or bundle of wires, 1 which is further provided with two secondary windings m n in opposite directions. The line wire a is connected to each of these secondary windings at the two extremities in n1 of opposite polarity and the opposite extremities m2 n2 are connected with the earth wires clt c ex in the manner already explained.

When operating the transmitting apparatus or when speaking into the microphone for example, induction currents are generated in the secondary windings m n and they then affect the receiving apparatus l at the receiving station as already stated. The primary winding and the two secondary windings may have the three wires wound in the same direction upon the soft iron core and the two extremities of the primary convolutions are connected with the local circuit in which is interpolated the transmitter while two extremities of opposite polarities of the secondary convolutions are connected to line and the two others to earth as previously explained.

In my improved transmitting, arrangement the. two earth wires at each. station must be the more separated from each other the longer the distance is between the two stations so that the resistance of the earth between the said earth-wires will be sufficient to cause the single line-wire to be traversed by the greatest possible quantity of the current.

In order to reduce as far as possible the distance between the earth-wires the beginning of the single line wire a and the wires d d1 leading to earth are advantageously removed at a distance front the transmitting instrument and receiving instrument respectively at the telegraphic or telephonic station and thus permit the two earth connections of the two telegraphic or telephonic stations to be placed nearer each other.

The telegraphic or telephonic station is then divided and the transmitting instrument is connected with the magnet with its earth connections and line wire z by two conducting wires k' k2 connected with the ends of the convolutions which generates Induction currents in the secondary windings m n (Figure 4).

The current sent into the conducting wires k1 k2 .and, passing through the convolutions k may itself be an induced current generated in the coil k3 when a current from the source of electricity c is passing through the primary coil or through the action of the transmitting microphone f/I for example.

In the case when the distance of the telegraphic or telephonic transmitting station from its earth connections is not too excessive the current traversing the conductors k le2 instead of. being an induction current may be furnished direct by the) source, of electricity of such station, and naturally transmitting instrument (microphone or key) and the source of electricity are then placed direct in the circuit leI k-S.

An interrupter It interpolated in the conductor k1 permits of cutting the circuit in leading to the secondary coil k3 and of closing the circuit for in conductor i leading to the conductor 3 in which is interpolated the receiving instrument j1.

Thus the coil k is either inductor or induction according to whether there is transmission or reception.

It is to be well understood that my system of transmission is entirely independent of the nature of the telegraphic or telephonic apparatus employed therewith, and that the source of electricity at the stations may be of any convenient kind,

---

Improvements in Connections of Telephonic and Telegraphic Instruments to Conducting Lines.
GB189706773

1897-03-15

Telegraph and telephone lines are arranged so that any pair of lines bearing instruments may be used as a lead or return for another set of instruments without interference. Thus, as an example, four metallic circuits carry four separate sets of instruments individually but may have circuits A and B, C and D, used as other metallic circuits, or A and B may form a lead and C and D a return for a seventh metallic circuit. The Specification describes telephone instruments as used on the metallic circuits and telegraph or telephone instruments inserted in the earth return circuits. Fig. 1 shows a pair of lines L<1>, L<2> forming a metallic circuit and capable of use as the line with an earth return through L<3>, L<3>, the lines L<2> being connected to the loop at the centre of the secondary coil S', S<2> of the induction coil X. The receiving-instrument is shown in a bridge, such as Z. The positions of the transmitting T and receiving R instruments may be reversed. Each side of a metal loop may also be used as the line with an earth return.

This invention relates to the connecting of telephonic and telegraphic instruments to conducting lines in such a manner that several telephonic and telegraphic messages can be simultaneously transmitted without interfering with one another.

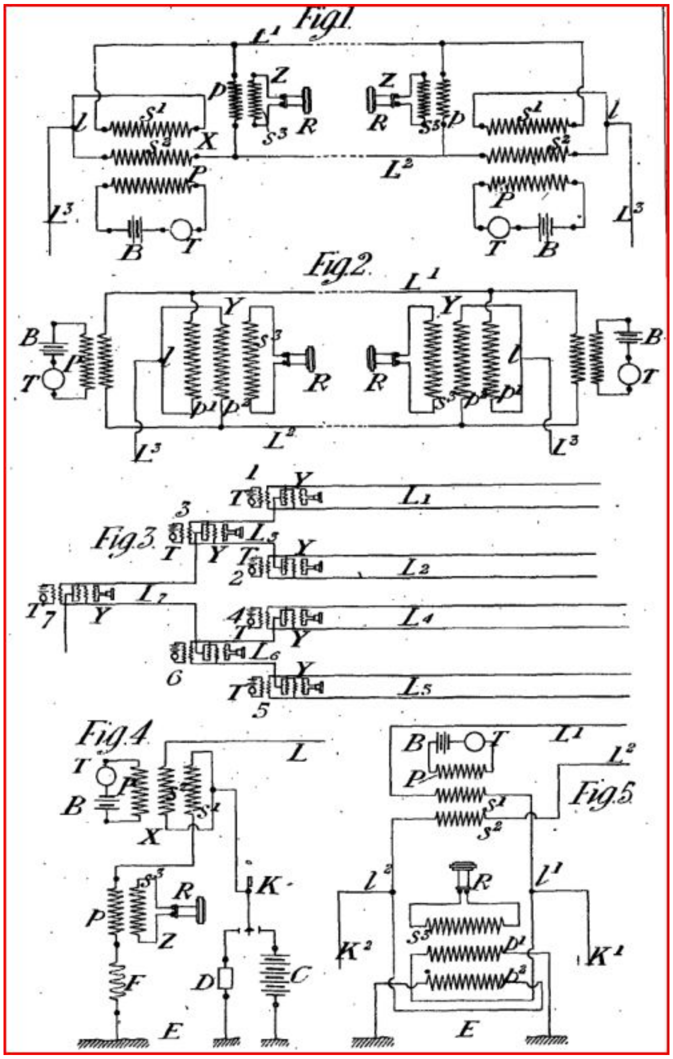
Fig. 1 of the accompanying drawings shews diagrammatically connections for a telephone and also for another telephone or telegraph to a double conducting line.

Fig. 2 shews a modification.

Fig. 3 shews how seven sets of the connections may be applied to four double conducting lines.

Fig. 4 shews the connections for a telephone and telegraph to a single line with earth return.

Fig..5 shews connections for telephoning over two telegraph lines one of them forming a metal return.



Referring first to Fig. 1 the two lines Ll L2 are at each end connected as shewn at X through two equal secondary coils 8 1 and s 2 wound with a primary coil P which is in circuit with a telephone transmitter T and local battery B.

The lines L1 L2 are so connected to the secondary coils 8 1 s 2 that the currents induced in the lines by the telephone transmitter are always in opposite directions.

The telephone receiver R, as shewn at Z, is in circuit with a secondary coil 8 3 wound with a primary coil p connecting the two lines L1 L2.

At a point l intermediate to the coils s1 s2 a third line L3 is connected, this line being employed for telephone or telegraph transmission. When either of the telephone transmitters T is employed, the induced currents pass through the primary coil p thus causing the receivers R to act. But should any current flow by L3 it must flow in opposite directions through 8 1 and s2, and therefore in the same direction along the lines L1 L2 so that it cannot influence the receivers R nor the transmitters T. At each end a line L3 may be connected as shewn by Y, Fig. 2, at l a point intermediate to two equal primary coils p1 p2 which connect the lines Ll LO and are wound with the secondary S3 of each telephone receiver R.

With connections thus arranged any current flowing in the same direction through the coils pl p 2 actuates the telephone receivers R, whereas a current from L3 flows in opposite directions through the coils pl p 2 and therefore is ineffective on the receivers R. By combining several ordinary transmitters T and several of the receiver arrangements marked Y in Fig. 2 with a number of double lines as shewn in Fig. 3, a number of messages can be sent over these lines without interfering with each other.

Thus referring to Fig. 3 the transmitter 1 works over the pair of lines L1 in the - usual way, one of these lines serving as metal return. In like manner the transmitter 2 works over the pair L2, transmitter 4 over the pair L 4 and transmitter 5 over the pair L 5. Again the transmitter 3 works through the pair of lines L 3 and the two pairs L 1 and L 2, one of these pairs serving as metal return.

In like manner the transmitter 6 works through the pair of lines L 6 and through the two pairs L 4 L 5. Finally the transmitter 7 works through the pairs of lines L 7 and through the two pairs L 3 and L 6 and the. four pairs L 1 L 2 L 4 and L 5, two of these pairs such as L 4 and L 5 serving as metal return.

Obviously this system may be duplicated, and reduplicated so that one transmitter can be made to work over 8 pairs or 16 pairs of lines or other multiple of 4.

As shewn in Fig. 4 a telephone and a telegraph are connected to one line L having earth return. In this case X and Z are the telephone arrangements so marked in Fig. 1, K is the key, C the battery and D the receiver for telegraphing in the connection of Z to earth there is an adjustable resistance F to balance that of the line. As shewn in Fig. 5 two sets of the telegraphic connections shewn in Fig. 4 and two lines Ll L2 which may be both to one place or each to a different place with earth return are combined with one telephone arrangement.

The transmitter T by its primary P induces currents in the secondaries $ 1 89 both in the same direction and therefore in opposite directions in the lines Ll L2. The currents being in the same direction in p1 and p2 act on the secondaries 1 3 of the receivers 1,. Currents from the telegraph gi dividing at 11 pass in opposite directions through sl and pl and therefore do not affect the telephonic receivers. And in like manner the currents from the telegraph K2 are ineffective on the receivers.

For the sake of clearness the primary and secondary coils have been shewn in the form of many lines side by side.

It is to be understood however that they are wound in each case all on one bobbin.

In Figs. 3,4 and 5 the arrangements are shewn at only one end of the conducting lines.

It is to be understood however that they are symmetrically repeated at the other end as shewn in Figs. 1 and 2.

COMPLETE SPECIFICATION.

This invention relates to the connecting of telephonic and telegraphic instruments to conducting lines in such a manner that several telephonic and telegraphic messages can be simultaneously transmitted without interfering with one other.

Figure 1 of the drawings accompanying my Provisional Specification shews diagrammatically connections for a telephone and also for another telephone or .telegraph to a double conducting line. Figure 2 shews a modification. Figure 3 shews how seven sets of the connections may be applied to four double conducting . lines: Figure 4 shews the connections for a telephone and telegraph to a single line with earth return. Figure 5 shews connections for telephoning over two telegraph lines one of them forming a metal return.

1 . Referring first to Figure 1 the two lines Ll L2 are at each end connected as shewn at X through two equal secondary coils s1 and 8 2 wound with a primary coil P which is in circuit with a telephone transmitter T and local battery B.

The lines Ll L 2 are so connected to the secondary coils 8 1 s'" that the currents induced in the lines by the telephone transmitter arc always in opposite directions.

The telephone receiver R, as shewn at Z, is in circuit with a secondary coil s3 wound with a primary coil p of high resistance connecting the two lines L1 L2.

At the point intermediate to the coils sr s 2 a third line L3 is connected, this line being employed for telephone or telegraph transmission. 'When either of tho telephone transmitters T is employed, the induced currents pass through tho primary coil p thus causing the receivers R to act. But should any current flow by L3 it must flow in opposite directions through sl and s2, and therefore in the same direction along the lines Ll L2 so that it cannot influence the receivers It nor the transmitters T. At each end a line L3 may be, connected as shewn by Y, Figure 2, at l a point intermediate to two equal primary coils p1 p2 which connect the lines L1 L2 and are wound with the secondary 8 3 of each telephone receiver R. With connections thus arranged any current flowing in the same direction through the coils yx actuates the telephone receivers R, whereas a current from L3 flows in opposite directions through the coils p1 p2 and therefore is ineffective on the receivers R. By combining several ordinary transmitters T and several of the receiver arrangements marked Y in Figure 2 with a number of double lines as shewn in Figure 3, a number of messages can be sent over these lines without interfering with each other.

Thus referring to Figure 3 the transmitter 1 works over the pair of lines L 1 in the usual way, one of these lines serving as metal return.. In like manner tho transmitter 2 works over the pair L 2, transmitter 4 over the pair L 4 and transmitter 5 over the pair L 5. Again the transmitter 3 works through the pair of lines L 3 and the two pairs L 1 and L 2, one of these pairs serving as metal return.

In like manner the transmitter ti works through the pair of lines JLA b and through the two pairs L 4 L 5. Finally the transmitter 7 works through the pairs of lines L 7 and through the two pairs L 3 and L 6 and the four pairs L 1 L 2 L 4 and L 5, two of these pairs such as L 4 and L 5 serving as metal return.

Obviously this system may be duplicated, and reduplicated so that) one transmitter can be made to work over 8 pairs or 16 pairs of lines or other multiple of 4.

As shewn in Figure 4 a telephone and a telegraph are connected to one line L having earth return. In this case X and Z are the telephone arrangements so marked in Figure 1, K is the key, C the battery and D the receiver for telegraphing.

In the connection of p to earth there is an adjustable resistance F to balance that of the line. As shewn in Figure 5 two sets of the telegraphic connections shewn in Figure 4 and two lines Ll L2 which may be both to one place or each to a different place with earth return are combined with one telephone arrangement.

The transmitter T by its primary P induces currents in the secondaries sl S2 both in the same direction and therefore in opposite directions in the lines L1 L2. The currents being in the same direction in pI and pS act on the secondaries i1 of the receivers It.

Currents from the telegraph K1 dividing at 1 1 pass in opposite directions through sl and I > I and therefore do not affect the telephonic receivers. And in like manner the currents from the telegraph K2 are ineffective on the receivers.

The connections of p1 and p2 to earth may have suitable resistances as shewn at F in Figure 4.

For the sake of clearness the primary and secondary coils have been shewn in the form of many lines side by side.

It is to be understood however that they are wound in each case all on one bobbin.

In Figures 3,4 and 5 the arrangements are shewn at only one end of the conducting lines.

It is to be understood however that they are symmetrically repeated at the other end as shewn in Figures 1 and 2.,

---

Perfectionnements aux bobines d'induction
FR382386

1908-02-05

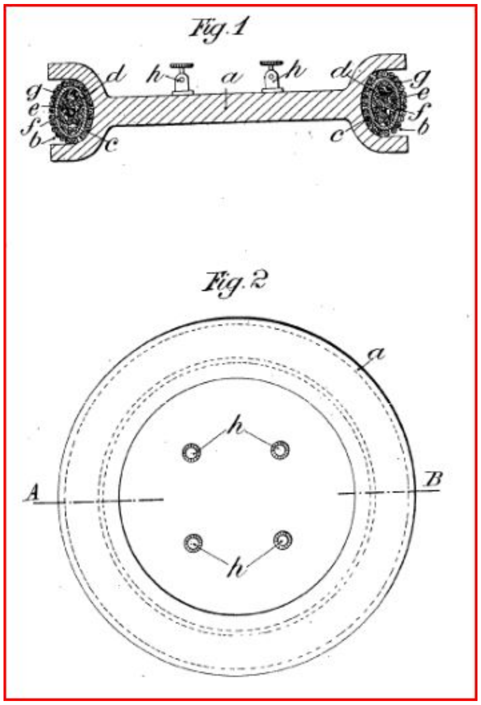
The present invention relates to an improved induction coil in order to obtain induction currents in very short periods. These currents, whose durations are extremely short 5, enjoy special properties which find application mainly in telegraphy and wireless telephony.

This induction coil is characterized by the absence of the magnetic core and the winding mode of the inductor and the armature on a short length coil, but a very large diameter, the inductor coil being virtually drowned in May 1 the armature winding.

The appended drawing schematic represents for example an induction coil according to the present invention.

FIG. 1 is a section along line A-20B of FIG. 2 ;

FIG. 2 is a plan.



As shown in these drawings, this coil has a very large diameter which can be up to several meters; 26 is drawing the round, but it could equally be square or affect any other polygonal shape. This reel is very long because all winding son are housed on its outskirts in a suitable groove b; it will be understood by 3o begins winding on the rim of this kind of pulley a first layer of wire induced E and then covered with a suitable insulating and d are wound over this insulating layer the inductor wire E which is covered another 35 isolated layer; we **réuuïï uêUi** the insulating layers d and f, so as to isolate the inductors e and ends the coil by an external winding armature wire g. ko

Is carried out in this way a large-diameter ring compound induced son c, g, containing a central core of an adequately insulated son inductors.

The machine has four terminals 5 h which two are used to secure the ends of the armature winding and the other two ends of the inductor winding.

We can arrange several induced son and son more inductors; in this case, each terminal 5o h will be replaced by a multiple switch that will bring together the different armatures on, and the different inductors on, either voltage or the contrary in quantity, following the effects that one wishes to obtain.

Dispositif de transmission téléphonique
FR377785

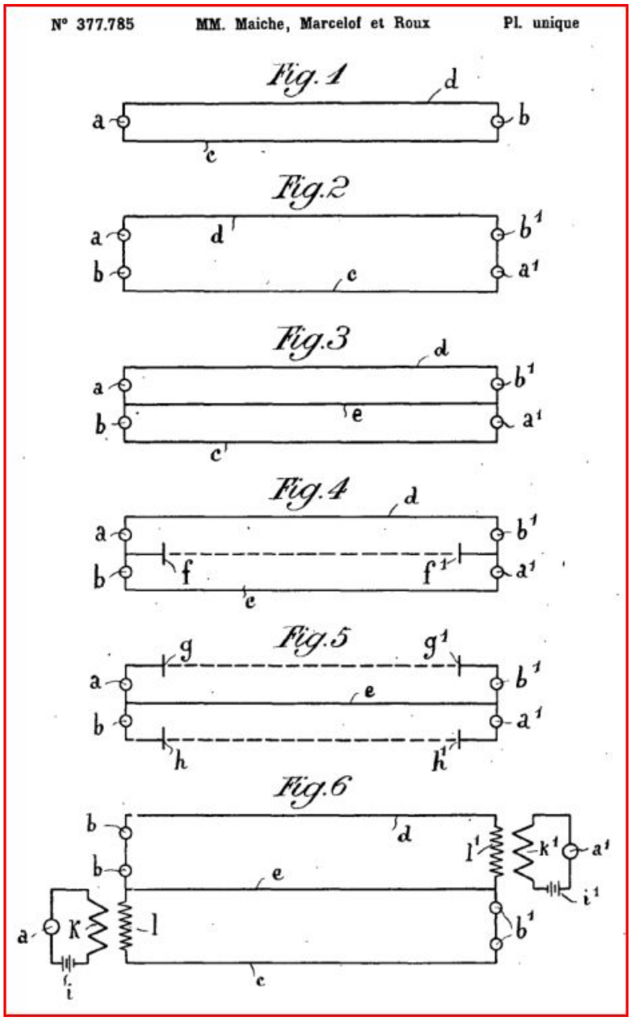
1907-09-14

Telephone transmission system of mounting each station transmitter and or serial receivers and to bring the two stations by three son line, including 5o first two respectively together the poles of the two stations and the third is mounted derivation at a point of each station caught between the transmitters and the receiver or receivers, one or even two of these three son may be replaced by equivalent landings.

The present invention provides a way to increase the distance at which it is possible to call or to increase the intensity of sound transmitted at a given distance 5.

When installing a regular telephone line, it is customary to bring the two stations using two wires, one for the second round for the return; at-10 there is no fear induction from neighboring lines, one connecting the two stations by a thread alone and return through the ground at each station.

FIG. 1 of the accompanying drawing shows the 15 most simple provision of a regular line with two son; there is one at each station magnetic phone, a1 met by both son line c and d; when speaking in the phone, the phone is 30 a1 receiver and vice versa; this provision is entirely satisfactory from the standpoint of the actual transmission, but it has the obvious disadvantage that the two parties can not break interfere, each necessarily listen to while the other speaks .



To overcome this disadvantage, it immediately offered to have each transmitter station a phone or a 1 and a receiver or telephone b bl, allowing 3 to the two interlocutors to talk while listening. This solution suffers a disadvantage from the standpoint of the transmission; in fact, as shown in Fig. 2, the four phone a, b, a}, bx 3 are mounted in series on the line cd, so that the sound transmitted by a transmitter has or a1 necessarily travels in addition interesting b1 or b receptor both other phones of the circuit. The telephone circuit thus unnecessarily h has a high resistance which reacts disadvantageously either on the possible length of the line cd, either the intensity of the sound transmitted to a given line length.

The present invention relates to a device easy positive h to remedy the drawbacks both of the two transmission systems according to Fig. 1 and 2 and make a new telephone transmission system providing both the benefits of the 5 two known systems.

As shown in Fig. 3, this invention is simply to dispose between the two stations a third e line wire terminating at each station between the telephone transmitter 5 tor a or a1 and the receiver phone b or b1. In these conditions the wall sent by "will be fully received by b1 without crossing unnecessarily b and a1 resistance and vice versa speech transmitted by a1 will be fully received by b.

The need for three son line c, d, e 5 is required when the line is around other transmissions; but when isolated, it can simplify the transmission as shown in Fig. k or 5.

According to FIG. h, the wire line drifted o-tion e is deleted and replaced by a ground f and f1 taken at each station between the transmitter and receiver.

In special cases, it is even possible to reduce the line to a single wire e in '5 with each station two landings g, h and # 1, h1), the receiver and transmitter are each disposed station in series between the two landings; under these conditions, the two conductors c and d are formed by o the ground and there is no longer a single line wire e.

In the above, to simplify the description and drawings, we assumed the exclusive use of magnetic phones; 5 Fig. 6 shows the circuit diagram in the case of induction phones. In this case each position i includes a battery, a transmitter microphone and primary k of an induction coil, mounted in series o on a closed circuit; the line circuit c, d comprises series headphones b, b and b1, b1 and side and ll of the coil. In this

If the invention is to attach the derivative e line wire between the two receivers b, b or i1, A1 on the one hand and the secondary or ll 35 on the other hand, as shown in FIG. 6.

The result of these provisions is summed up by the possibility of quadrupling of the intensity of the reception for a given length of line, or the length of the line Zio maintaining the same intensity.

Nouveau mode de transmission sans fils des courants télégraphiques et téléphoniques en employant comme conducteurs la terre et l'eau
FR320267

1902-12-05

To understand our invention, it is good to remember that in an ordinary telegraph line a thread, more or less isolated, from a point to another, communicates with earth at each end. A power source; and a transmitter unit are sandwiched between the starting line and earth. Upon arrival, a receiver also communicates with the line and the earth.

We know that each of the posts supporting the line passes a small amount of power that is lost in the ground. Large amount of current is now lost all **plus 1 large 5** that the distance between stations is itself larger and, consequently, the number of' poles is higher. Loss can become considerable, without preventing transmissions. It may even happen that the ao thread without being broken, drags on earth there for a certain length of son'parcours and continues to allow the current of a shift to another, albeit very weakly,

The experience proved us uninsulated conductor could even, for certain distances, be simply placed on the ground and that transmissions would nevertheless be possible.

We are able to continue, transmit signals is greatly increased if, at each end, the uninsulated wire touching the ground, met in a well-insulated wire that extends the line to a ground to the point where so are transmitters and receivers.

It is understood that the ground at the end of a secluded part forces the return current from sinking into the depths of the earth ho and that, consequently, there is an infinitely small closure point where the uninsulated wire touches the ground. In other words, the loss suffered in ground contact, the uninsulated wire, is even less than each end of uninsulated wire so is an insulated wire from the ground at a greater distance.

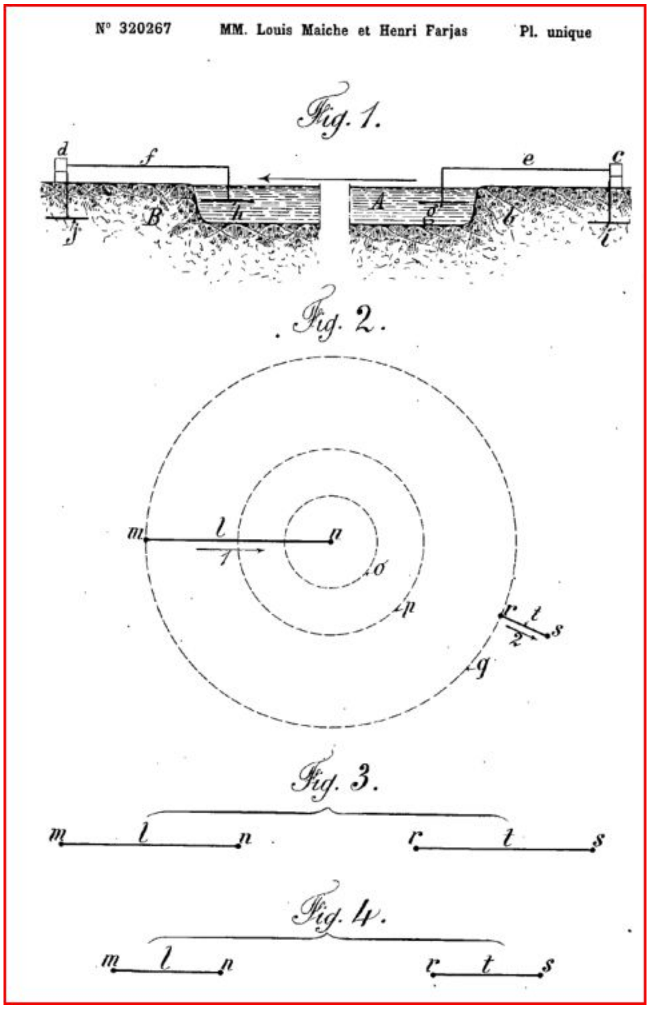
Hence, if the lead wire, instead of iron, consisting of a much less conductive material, coal, for example, everything would be the same way. We also recognized that even when iron, coal or other similar material, are replaced by placed water, salt if possible, and, consequently, by a stretch of sea or any other part of sea whose geographic provision lends itself to this kind of installation.

When it comes to cross an arm of the sea, the isolated line extension is placed preferably in the direction of the straight line through the two points to be connected.

In case one transmission on a role, isolated leagues will be perpendicular to the straight line joining the two stations.

Isolated lines will not be too long, and therefore, will provide not only coast to coast, but between two points inland. The thickness of the salt water layer being at even greater depths, only about the thickness of the land mass, the proportions remain between water and adequate the earth so that water plays exactly the same role that the uninsulated conductor touching the ground.

To make our evplications as clear as possible, we have shown diagram-matically, in the accompanying drawing, an installation in which our invention is applied.



A is the sea (Fig. I) and 13 b are both shores, c and d both stations, e and f insulated, and the plates located in the water, i and it updates earth.
We see that the sea is an extension isolated son e and f, and it plays the role of an uninsulated conductor based on floor.

To make it clear how 3 o operates the propagation of electric currents, we assume an isolated line (Fig. A) within two earthed m and n. If the current is moving in the direction of the **llèche**, electricity arriving ashore in n flourishes spheres 3.) concentric o, p, q, etc., all points of each sphere simultaneously receiving the same amount of electricity if the propagation medium is uniform. Be grounded in r therefore receive the current along the earth m, r and if this land is connected by a line by t, s land to another, even very close to her, the current finding less resistance in the isolated line in the middle (Jun separates the two nets land, will follow this line, as shown in llèche a. It will be thus possible to establish a wireless communication between any point of the line / on which find transmitting devices, and any point on line T which will be **appareds** receptors.

To establish simultaneously on each of the leagues and t, a position transmitter and a receiver will require that the line is the same length as the line 1, J J as shown in Fig. 3.

If the medium is found to be twice as conductor between h and r between m and n, on the one hand, and between r and s on the other hand, the lines l and t may have as half the length of the distance between the points n and r (fig.û).

Of course, transmissions based on the principle that we have indicated, may be made by taking as con- bo different producers, not only the earth and the sea water, but the earth and air, land in this case, acting as a better conductor brought by the air; the insulated wire from the earth lead to the air at each station 7. tion to a more or less remote distance according to the distance that would take. It is obvious that the latter provision, the sea and fresh water advantageously replace the earth. 7°

In summary, we claim as our exclusive property, the new method, described above, transmission without telegraph and telephone currents, said transmission mode of making pass in a conductive medium the current emitted by the base station and to receive on arrival in this current an insulated wire of suitable length, which are sandwiched the receivers and resulting in a second medium whose specific conductivity is less than that of the first medium, but passes the total quantity of electricity because of its mass which is greater than that first medium, an insulated wire, on which the transmitting devices is also leading into the second medium, so that the first medium is an extension of two isolated lines, and the second medium acts as the return wire, the two isolated lines to be used both for shipping and for the reception.

Un nouveau mode de transmission et de réception des courants télégraphiques et téléphoniques sans autre conducteur que la terre ou l'eau

FR318007

1902-10-03

In an electrical circuit consisting of a power source and a metallic conductor whose ends are grounded, which closes the circuit, the earth acts as 5 driver not only a straight line between the two landings, but on a almost infinite extent; However, with a power density decreasing in proportion to the distance.

If parts of the ground are better conductors than others (because of the moisture, the saltiness of the water or any other cause) the current preferably passes through these parts describing curves or bends as does a river following the slopes of the terrain.

It follows that if, on part of the land used as return conductor, it artificially creates a better conductor line as the earth, it will be traversed by the current in preference to any other lower conductive part.

The effect is much more complete and can collect the current and note its existence when the best conductive line is insulated from earth and communicates with it by its ends. The current that would have crossed the land finding a wise not easier by the wire preferably follows and restores much faster electrical neutrality of the ground. It is isolated by cutting the line at any point that can be inserted in the course of the current instruments (telegraphic or telephonic receivers) that can detect its existence.

It is understood that if the isolated artificial line is a very good conductor, if its ends are connected to metal surfaces large enough in contact with the ground, the closing of the circuit will cause the ground to be in a state of electrical neutrality absolute.

Under these conditions, if a current electric is sent intermittently in the metal line, charge the earth, for each issue, a certain amount of electricity instantaneously discharge into the isolated artificial line.

Experience has shown that these phenomena can occur even when there is almost no gap between the two landings transmitter station or between two plates that collect the color rant crossing the line isolated the receiving station, to the condition that at each station the plates which lead to the two lands are carefully insulated from each other by means of a sufficiently thick insulating separation that no induction effect or condensation on one another can occur, and fairly large compared to the dimensions of the plates to prevent current from closing on itself too close to the to start. The current is so obliged to flourish "right and left of the landings, and the point where the positive and negative electric waves begin to reach is considerably related. I can further increase the desired effect by minimizing the current closure on itself through a number of insulating walls arranged below the plates to prevent **farm-i o ture** of the circuit by the depth of the earth, on the side opposite that in which the transmission must be received and, if necessary, above the plates.

In general, the plates will be placed vertically on either side of an insulating wall, their smaller dimensions being turned to the opposite position.

I can also use a wide insulating tube divided in two by a thick wall normal to isolated generators. The plates will be set back to back on either side of this partition in the interior of the tube and placed in communication with the outer conductor through insulated **son**.

The tube may be straight, or consists of two parts forming between them an angle properly calculated so that the circuit is closed by the earth is done by almost entirely in the **3 o** where the current is sent.

It is obvious that the installation is completed by transmitters and telegraph or telephone receivers that may be any, as the source of electricity.

I claim as my exclusive new property above described transmission and reception of telegraph and telephone currents without other driver as land or water, said system of separating the two landings each position by established insulating material to prevent the production of induction phenomena of condensation and the circuit closing on or by the depth of the earth, and force the air to flourish right and left, so that they can begin to get to and distant from the transmitter station, the two earthed of each position can thus without drawbacks, are moved towards one another until they fit on either side of the same insulating wall.

DNA Molecules Can 'Teleport,' Nobel Winner Says
By John E Dunn, Techworld.com

A Nobel Prize winning biologist has ignited controversy after publishing details of an experiment in which a fragment of DNA appeared to 'teleport' or imprint itself between test tubes.

According to a team headed by Luc Montagnier, previously known for his work on HIV and AIDS, two test tubes, one of which contained a tiny piece of bacterial DNA, the other pure water, were surrounded by a weak electromagnetic field of 7Hz.

Eighteen hours later, after DNA amplification using a polymerase chain reaction, as if by magic the DNA was detectable in the test tube containing pure water.

Oddly, the original DNA sample had to be diluted many times over for the experiment to work, which might explain why the phenomenon has not been detected before, assuming that this is what has happened.

The phenomenon might be very loosely described as 'teleportation' except that the bases project or imprint themselves across space rather than simply moving from one place to another.

To be on the safe side, Montagnier then compared the results with controls in which the time limit was lowered, no electromagnetic field was present or was present but at lower frequencies, and in which both tubes contained pure water. On every one of these, he drew a blank.

The quantum effect - the imprinting of the DNA on the water - is not in itself the most contentious element of the experiment, so much as the relatively long timescales over which it appears to manifest itself. Quantum phenomena are assumed to show their faces in imperceptible fractions of a second and not seconds minutes and hours, and usually at very low temperatures approaching absolute zero.

Revealing a process through which biology might display the underlying 'quantumness' of nature at room temperature would be startling.

Montagnier's experiment will have to be repeated by others to have any hope of being taken seriously. So far, some scientists have been publically incredulous.

"It is hard to understand how the information can be stored within water over a timescale longer than picoseconds," said the Ruhr University in Bochum's Klaus Gerwert, quoted by New Scientist magazine, which broke the story (requires registration).

What does all of this mean? It could be that the propagation of life is able to make use of the quantum nature of reality to project itself in subtle ways, as has been hinted at in previous experiments. Alternatively, it could be that life itself is a complex projection of these quantum phenomena and utterly depends on them in ways not yet understood because they are incredibly hard to detect.

Speculatively, (and Montagnier doesn't directly suggest anything so unsubstantiated), it could also be the little-understood quantum properties of the water molecule and not just its more obvious chemical bonding properties that gives it such a central role in the bio-engineering of life-forms. Water might be a good medium in which DNA can copy itself using processes that hint at quantum entanglement and 'teleportation' (our term).

Montagnier's paper goes on to discuss the phenomenon he claims to have uncovered using 'quantum field theory' within the context of his personal interest, disease propagation.

Abstract. Some bacterial and viral DNA sequences have been found to induce low frequency electromagnetic waves in high aqueous dilutions. This phenomenon appears to be triggered by the ambient electromagnetic background of very low frequency. We discuss this phenomenon in the framework of quantum field theory. A scheme able to account for the observations is proposed. The reported phenomenon could allow to develop highly sensitive detection systems for chronic bacterial and viral infections.

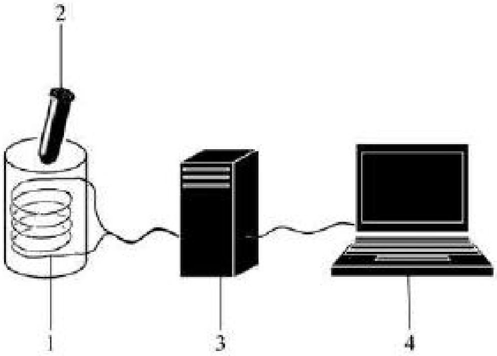

Figure 1. Device for the capture and analysis of em signals. (1) Coil made up of copper wire, impedance 300 Ohms. (2) Plastic stoppered tube containing 1 ml of the solution to be analyzed. (3) Amplifier. (4) Computer. From Ref. 1

Here is a brief summary of the laboratory observations, which are described in more detail in [1, 2, 3]:

1) Ultra Low Frequency Electromagnetic Waves (ULF $500-3000\ Hz$) were detected in certain dilutions of filtrates ($100\ nm$, $20\ nm$) from cultures of micro-organisms (virus, bacteria) or from the plasma of humans infected with the same agents (Fig. 2). Same results are obtained from their extracted DNA.

2) The electromagnetic signals (EMS) are not linearly correlated with the initial number of bacterial cells before their filtration. In one experiment the EMS were similar in a suspension of *E. coli* cells varying from 10^9 down to 10. It is an all or none phenomenon.

3) EMS are observed only in some high water dilutions of the filtrates. For example, from 10^{-9} to 10^{-18} dilutions in some preparations of *E. coli* filtrates.

4) In the case of *M. pirum*, an isolated single gene (adhesin, previously cloned and sequenced) could induce the EMS. As the gene was cloned in two fragments, each of the isolated fragments was able to generate EMS, suggesting that a short DNA sequence was sufficient to induce the signals. Similarly, a short HIV DNA sequence (104 base pair) is found to be sufficient to produce the EMS.

5) Some bacteria are not producing EMS: this is the case of probiotic bacteria such as *Lactobacillus* and also of some laboratory strains of *E. coli* used as cloning vector.

6) These studies have been extended to viruses, although not all the viral families have been explored. Similar EMS were detected from some exogenous retroviruses (HIV, FeLV), hepatitis viruses (HBV, HCV), and influenza A (in vitro cultures). In general, EMS are produced by 20 nm filtrates of viral suspensions or from the extracted DNA: a question remains for RNA viruses (HCV, influenza) as to whether the RNA from the mature viral particles is a source of EMS, or not. In the case of HIV, EMS are not produced by the RNA of viral particles, but rather are produced by the proviral DNA present in infected cells. In the case of bacteria, EMS are produced by 100 nm filtrates and not by 20 nm filtrates, indicating that the size of the structures producing EMS is ranging between 20 and 100 nm. This justifies the name of nanostructures. These studies are highly suggestive that one is dealing with nanostructures made of water. Highly purified water samples are used, although one cannot exclude the role of minimal traces of impurities. The EMS production by the nanostructures is resistant to: Rnase treatment, Dnase (while this will destroy the DNA at the origin of EMS), Protease (proteinase K), Detergent (SDS). However, they are sensitive to heat (over 70 $^\circ C$) and freezing (-80 $^\circ C$). This sensitivity is reduced when dealing with purified short DNA sequences. The technical conditions for EMS induction is summarized by the following list:

- Filtration: $\frac{450}{100}$ nm for bacterial DNA, $\frac{450}{20}$ nm for viral DNA
- High dilutions in water
- Mechanical agitation (Vortex) between each dilution
- Excitation by the electromagnetic background of extremely low frequency (ELF), starting very low at 7 Hz. The excitation is not induced when the system is shielded by a mu-metal cage.

The stimulation by the electromagnetic background of very low frequency is essential. The background is either produced from natural sources (the Schumann resonances [4] which start at 7.83 Hz) or from artificial sources.

REMOTE TRANSMISSION OF ELECTROMAGNETIC SIGNALS INDUCING NANOSTRUCTURES AMPLIFIABLE INTO A SPECIFIC DNA SEQUENCE

Inventor: MONTAGNIER LUC // LAVALLEE CLAUDE

A general method for identifying both known and unknown DNA sequences at the origin of EMS, including DNA sequences in the plasma of patients suffering of chronic diseases such as Alzheimer, Parkinson, multiple sclerosis, rheumatoid arthritis, and other similar diseases, disorders and conditions. The invention is based on the discovery that: (1) The nanostructures induced by DNA sequences in water or other dipole solutions can faithfully reflect the information contained in these sequences at dilutions which do not contain anymore of that DNA, as evidenced by the fact that it can be retranscribed into the same DNA sequence by the polymerases and reagents used in classical polymerase chain reaction (PCR); (2) this information can be transmitted at a distance in water or other dipole solutions by EMS emitted by the nanostructures; and (3) EMS signatures of nanostructures containing this information can be detected, stored, transmitted, transduced and imprinted in water or other dipole solutions.

BACKGROUND OF THE INVENTION

[0004] 1. Field of the Invention

[0005] Induction, detection and transmission of electromagnetic signals (EMS) from self-replicating molecules like DNA.

Transduction of EMS from an EMS positive (EMS+) sample to a naïve, unsignalized sample. Methods for identifying a molecule like DNA in a sample by transducing its EMS signature to water, amplifying the signalized water to produce a DNA. Methods for detecting DNA associated with a condition, disorder or disease of incomplete or unknown etiology by inducing specific EMS emission from the sample at a particular frequency, signalizing a naïve sample with the emitted EMS, and detecting an EMS in the signalized water and/or amplifying the signalized water using a DNA amplification technique and analyzing the products of the amplification.

[0006] 2. Description of the Related Art

[0007] The inventors have previously described a method for selectively detecting DNA sequences of pathogenic microorganisms by their emission of low frequency electromagnetic waves (EMS) in water dilutions. U.S. application Ser. No. 12/560,772, filed Sep. 16, 2009, entitled "System and Method for the Analysis of DNA sequences in Biological Fluids" discloses a method for detecting electromagnetic waves derived from bacterial DNA, comprising extracting and purifying nucleic acids from a sample; diluting the extracted purified nucleic acids in an aqueous solvent; measuring a low frequency electromagnetic emission over time from the diluted extracted purified nucleic acids in an aqueous solvent; performing a signal analysis of the low frequency electromagnetic emission over time; and producing an output, based on the signal analysis, in dependence on the DNA in the sample. The products and procedures as well as other subject matter disclosed in this patent application are expressly incorporated by reference.

[0008] Methods for detecting some low electromagnetic frequency electromagnetic signals in diluted filtrates of the culture medium of certain bacteria and viruses, as well as in diluted plasma of patients infected by the same agents are disclosed by U.S. application Ser. No. 12/097,204, PCT/FR2007/001042, filed Jun. 22, 2007, and U.S. application Ser. No. 12/797,826, filed Jun. 10, 2010 each of which expressly incorporated by reference in their entirety. The electromagnetic signals (EMS) were believed to be produced by certain defined nanostructures induced by the microorganism, in high dilutions in water, after the microorganism had been removed by filtration.

[0009] Materials and methods for detecting replicating molecules such as DNA and methods for EMS detection as well as other subject matter pertinent to the present invention disclosed in these documents is incorporated by reference to the following documents:

[0023] In some instances, it was demonstrated that the EMS could originate from specific genes or even from some fragmented DNA sequences. This was discovered to be the case for the adhesin gene of Mycoplasma pirum (U.S. Ser. No. 12/097,204, filed Dec. 14, 2006) and of the LTR (Long terminal repeat), nef and pol genes of Human Immunodeficiency Virus (HIV) (U.S. 61/186,610, filed Jun. 12, 2009 & U.S. Ser. No. 12/797,826, filed Jun. 10, 2010). However, for many microbial agents or diseases of unknown origin or etiology this identification was not possible. Consequently, the inventor developed new methods, disclosed herein for detecting and identifying biological molecules, specifically DNA or other nucleic acids, associated with these other disease or disorders.

BRIEF SUMMARY OF THE INVENTION

[0024] There are several nonlimiting aspects to the invention.

[0025] (1) A method for producing a solution, such an aqueous solution like water that contains nanostructures that characterize a molecule like DNA. This method involves dilution, usually serial dilution, of a sample containing DNA and agitation of the sample between dilutions to produce the water nanostructures.

[0026] (2) Measuring EMS characteristic of a molecule like DNA or of its nanostructure in an originating sample and transducing this signal into a second receiving sample, usually water that does not emit the EMS signal. This is performed without contacting the originating sample and the receiving sample.

[0027] (3) Electronic transmission of a detected or recorded EMS signal to a remove location and optionally imprinting it on a naïve sample and/or recovering DNA or other replicating molecule from the imprinted naïve sample.

[0028] (4) Detecting DNA or DNA like molecules in a sample suspected of containing a particular agent, like HIV or Borellia.

[0029] (5) Identifying DNA or similar molecules present in an unknown sample, such as from a sample from a subject having a disease of unknown etiology.

[0030] (6) Devices that detect, induce, transduce or transmit EMS signals.

BRIEF DESCRIPTION OF THE DRAWINGS

[0031] FIG. 1 illustration of apparatus and method for EMS signal transduction. Tube 1 contains a sample of DNA dilution positive for EMS. Tube 2 initially contains unsignalized or naïve water. After exposure inside coil to 7 Hz excitation signal, naïve sample converts and emits EMS when diluted up to D4 (10<-4>). D-4 LTR HIV DNA (104 bp) 7 Hz, 18 Hrs and then PCR (35 cycles) from D2 to D15 after filtration 450 and 20 nM; DW: Distilled Water; FD2: Dilution 10<-2 >after filtration at 450 nM and 20 nM.

[0032] FIG. 2 Detection by PCR of HIV1 LTR transduction in water.

[0033] FIG. 2A: HIV1 LTR DNA D6 (EMS positive) dilution was used as emitter using excitation frequency of 7 Hz during 18 hours in the apparatus described in FIG. 1 and placed close to the water receiver Tube 2. Like the latter, it was then diluted at 10<-2>, refiltered by 450 nM and 20 nM filters and diluted to 10<-15>. Each dilution was then amplified by PCR 35 cycles. Note the DNA bands detected at dilutions D2, (FD2), D3, D4, and D5.

[0034] FIG. 2B shows transmission in water of D6 dilution of LTR HIV DNA (104 bp). Method was performed using excitation frequency 7 Hz, an 18 hr exposure followed by 35 cycles of PCR from D-2 to D-15 after 450 nM and 20 nM filtration. DW denotes distilled water control. FD2-FD15, dilution to 10<-2>-10<-15>. Transmission in

water of D-4 LTR HIV DNA (104 bp) 7 Hz, 18 Hrs and then PCR (35 cycles) from D-2 to D-15 after filtration 450 and 20 nM. Note: DNA band formation is up to D-8.

[0035] FIG. 3. Illustration of method to generally identify an unknown DNA sample. DNA in plasma sample is induced to emit EMS and the EMS signal is transduced to a separate sample of water to produce signalized water. Water signalized by EMS is serially diluted and PCR is performed using random tag primers producing DNA. The sequence of the DNA is determined and can be compared to known DNA sequences to identify the DNA in the unknown sample. Example 3 describes such a method.

[0036] FIG. 4. Detection of unknown DNA sequences from a patient plasma DNA sample. DNA was extracted from the plasma of a patient suffering from chronic Lyme disease. A D9 (10<-9>) EMS positive dilution of the original DNA sample was transduced into water by excitation at 7 Hz for 18 hrs. PCR was performed on dilutions of the receiving water sample. FIG. 4 shows agarose gel electrophoresis of the transduced DNA obtained after PCR with Tag8N primers followed by a second PCR with the Tag primers only. Three DNA bands were observed. As shown at the left, results obtained when the tube of D9 DNA and the tube of water are placed side-by-side. At right, results obtained when the two tubes were placed at a distance of 4 cm from each other during the 7 Hz excitation. Dw denotes control, naïve, unsignalized water. Dw vor: denotes control naïve, unsignalized water agitated with a vortex. D0: water that was transduced but not diluted. D2 NF: same as D0 but diluted by 1:100 (D2). D2 same as D2 NF, but filtered. D3, D4, D5 represent further serial dilutions of D2 to factors of 1:1,000 (D3); 1:10,000 (D4) and 1:100,000 (D5). All serial dilutions were vortexed between each 1:10 dilution.

DETAILED DESCRIPTION OF THE INVENTION

[0037] Definitions:

[0038] Nucleic acid: Includes single stranded, double stranded DNA, and RNA as well as modified polynucleotide sequences. Biological samples containing DNA associated with a disease or disorder are generally isolated or recovered in double stranded form.

[0039] Self-replicating molecule: A molecule, such as DNA, that under appropriate conditions, can reproduce the information content of its primary, second, tertiary or quaternary structure. For example, a DNA molecule can replicate itself in the presence of the appropriate enzymes, primers and nucleotides.

[0040] DNA Amplification: Methods for amplifying nucleic acids are known. Conventional methods including polymerase chain reaction (PCR) are known and are also incorporated by reference to Current Protocols in Molecular Biology (updated Apr. 5, 2010), Print ISSN: 1934-3639; Online ISSN: 1934-3647.

[0041] Nanostructures: These structures of water are induced by biological molecules like nucleic acids such as single stranded or double stranded DNA. While not being bound to any particular theory, according to the physical theory of diphasic water, filtration and mechanical agitation (succussion) are believed to induce in water a low energy potential favoring the formation of quantum coherent domains. These domains will become replicas of a DNA molecule and vibrate by resonance when properly diluted and excited; see Del Guidice, et al., Water as a Free Electric Dipole Laser, Phys. Rev. Lett. 61, 1085-1088 (1988). Hydrogen bonding networks in liquid water, such as those described by Cowan, et al., Nature 434 (7030): 199-202 (2005) have not been associated with nanostructures.

[0042] Serial Dilutions: Serial dilution is a well-known technique and involves the stepwise dilution of a substance, such as DNA, in a solvent, such as water, saline solution, aqueous buffer, or an aqueous alcohol solution. Generally, serial dilutions as performed herein are stepwise dilutions by a factor of 10, or dilution of 1 part of a more concentrated solution in 9 parts of a solvent.

[0043] EMS: Electromagnetic signal. EMS in the context of the methods herein generally involves those having frequencies ranging from 0 Hz to 20,000 Hz as well as all intermediate subranges and values. Components of the ambient electromagnetic field include Schumann resonances which represent a set of spectrum peaks in the extremely low frequency (ELF) portion of the Earth's electromagnetic field spectrum. Schumann resonances are global electromagnetic resonances excited by lightning discharges in the cavity formed by the Earth's surface and the ionosphere and are the principal background in the electromagnetic spectrum between 3 and 69 Hz. A representative Schumann resonance peak occurs in the Earth's electromagnetic spectrum and an ELF of about 7.83 Hz. By comparison, 60 Hz cycling of electricity is used in North America and 50 Hz elsewhere in the world.

[0044] EMS detection. Any suitable means for interrogating a sample and measuring its EMS may be employed. Exemplary systems, methods, and apparatuses for this purpose are disclosed by Butters, et al., WO 03/083439 A2, and are incorporated by reference to this document. Generally, these procedures will involve placing a sample into a container having electromagnetic and magnetic shielding, a source of Gaussian noise for injection in to the sample, a detector for detecting an electromagnetic time-domain signal composed of sample source radiation superimposed on the injected Gaussian noise, and a storage device for storing the time-domain signal and a time-domain signal separately detected from the same of a similar sample.

[0045] EMS Signature: The EMS characteristic of a particular biological molecule or a time domain signal associated with a material of interest. EMS signatures for various biological molecules are disclosed by U.S. Ser. No. 12/797,826, filed Jun. 10, 2010. Such EMS signatures as well as methods for producing samples suitable for EMS detection and methods for detecting an EMS signature are incorporated by reference to this patent application.

[0046] An EMS Signature of a particular molecule can be represented by a characteristic electromagnetic time domain signal. An EMS Signature may be recorded and replayed, undergo signal transformation or processing, or be transmitted.

[0047] Excitation Frequency: A frequency used to excite a sample in which an EMS signature has been detected and induce an EMS signature in a sample previously devoid of the EMS signature, e.g., pure water. These frequencies include those of 7 Hz or above, e.g., 7, 8, 9, 10, 11, 12, 13, 14, 15, 20, 30, 40, 45, 50, 55, 60, 65, 70 or more.

[0048] Originating Sample: A biological sample that contains an EMS signature, such as one characteristic of one or more biomolecules. An example would be a sample containing an EMS signature characteristic of DNA derived from human immunodeficiency virus.

[0049] Receiving or Signalized Sample: A sample, such as water or another aqueous buffer or dipole that has acquired or been imprinted with a nanostructure corresponding to a biological molecule, such as DNA. Methods for producing signalized water by serial dilution and agitation in water or in an aqueous solvent are disclosed herein.

[0050] Pathogenic Disease: Disease caused by or associated with a pathogen, such as a pathogenic parasite, yeast or fungus, bacterium, virus or infectious protein, such as a prion. Examples include parasitic diseases such as malaria or trypanosomiasis, fungal diseases, such as infections caused by or associated with Aspergillus, Candida, Histoplasma, Pneumocystis, Cryptococcus, Stachybotrys (black mold), bacterial infections such as Lyme Disease, sexually transmitted bacterial infections, tuberculosis, viral infections, including HIV infection, herpes virus infection, or hepatitis, and prion associated diseases such as Creutzfeldt-Jakob disease and so-called Mad Cow disease.

[0051] Autoimmune Disease, Degenerative Disease, Disorders or Conditions: These diseases, disorders or conditions may or may not have been previously associated with a particular biological molecule, such as a particular DNA molecule or its corresponding water nanostructure. Examples include allergic conditions, multiple sclerosis, rheumatoid arthritis, disorders associated with transplantation or replacement of body parts, Alzheimer's disease, Parkinson's disease and other diseases or disorders of unknown or incomplete etiology, such as Chronic Fatigue Syndrome, Gulf War Syndrome, or with exposure to particular biological, chemical or physical agents or with the sequela of such exposure.

[0052] Representative embodiments of the invention are described below.

[0053] (i) Originating and Signalized Samples.

[0054] Test samples used to produce an EMS will contain DNA or other replicating biological molecules that can form nanostructures or can be naïve samples signalized by EMS transduction to emit EMS or contain nanostructures representative of the DNA or other molecule. Representative test samples include blood, plasma, serum, CSF, joint fluid, saliva, mucous, semen, vaginal fluid, sweat, urine, and feces. Tissue samples and samples from other sources, including laboratory or hospital sources, foods, drinks and potable water may be used. These may be diagnostic samples, such as those obtained from a subject known to have or suspected of having a particular conditions, disorder or disease like AIDS or Lyme disease. Alternatively, they may be obtained from subjects having or suspected of having a condition, disorder or disease of unknown etiology, such as a parasitic or fungal disease or disorder, bacterial disease or disorder viral disease or disorder, an autoimmune disease, disorder or condition, diseases such as Alzheimer's Disease or Parkinson's Disease.

[0055] To produce a sample that emits detectable EMS, a test sample undergoes dilution, usually serial dilution, and agitation preferably between each serial dilution. A test sample is usually diluted by a factor of 10<3>, 10<4>, 10<5>, 10<6>, 10<7>, 10<8>, 10<9 >10<10>, 10<11>, 10<12>, 10<13 >or more. Though any intervening factor of dilution or other degrees of dilution that produce detectable EMS may also be used. The beginning concentration of a nucleic acid in a sample prior to dilution generally ranges from 1 ng/ml to 4 ng/ml.

[0056] Solutions for dilution and agitation as well as for containing an originating or receiving sample are preferably water, but other aqueous or dipolar solutions may be employed so long as they can provide nanostructures representative of DNA or other replicating molecules or induce detectable EMS when used. Examples of solutions include water, or other aqueous solutions, such as normal saline, phosphate buffered saline, physiologically acceptable aqueous solutions, buffered aqueous solutions, or alcohol and water mixtures, including 10, 20, 30, 40, 50, 60 and 70% or more of ethanol or other alcohol solutions or other solvents selected on a basis of their relevant properties depending on the molecule to be tested, may be employed in the methods described herein.

[0057] In some applications, control samples are required. The type of control sample may be selected by one of skill in the art depending on the particular application but in general will not emit the EMS signature of the molecule of interest or contain nanostructures corresponding to it. Often, such controls will constitute pure, unsignalized water, distilled water or pyrolyzed water or other solutions known to be nucleic acid free.

[0058] Signalized samples or solutions producing an EMS signature should not be boiled, heated or frozen for long periods of time so as to preserve the EMS signatures or nanostructures they contain. Preferably, these samples or solutions should be stored above freezing and less than 40[deg.] C.

[0059] Various forms and time periods for agitation are contemplated and are incorporated by reference to the documents mentioned above. Vortexing for a period of 15 seconds between serial dilutions is one representative method for producing a sample emitting detectable EMS.

[0060] (ii) EMS Transduction. The invention also relates to a method for producing an EMS signature in an aqueous buffer comprising placing an originating (EMS+) sample in an aqueous buffer and a receiving sample not having the EMS signature next to each other inside of an electromagnetically shielded container, applying an electromagnetic field for a time and under conditions sufficient to transfer the EMS signature from the originating sample to the receiving sample. The electromagnetic field is generally applied by a coil, such as a copper coil, located inside of an electromagnetically shielded container. Coils made of other electrically conducting metals or alloys may be employed or other devices that produce similar electromagnetic flux. The electromagnetic field can be applied to the sample for a time period ranging sufficient to produce an EMS signature, for example, from 12 to 24 hrs although other suitable time periods may be selected based on the nature of the sample, the sample dilution and the physical characteristics of the apparatus. Exposure time is chosen based on the amount of time required for transfer to occur. Some representative times include >0, 1, 2, 3, 4, 4-8, 8-12, 12-18, 18-24 and 24-48 hrs or longer. Signalized samples produced by this method as well as nucleic acids like DNA amplified from a signalized sample are also contemplated. Alternatively, an EMS signature may be imprinted in water or another aqueous buffer by contacting the one or more receiving samples with a recorded or transmitted and optionally amplified EMS signature previously obtained from an originating sample in an aqueous buffer having an EMS signature, for a time and under conditions sufficient to imprint the recorded or transmitted EMS signature of the originating sample onto the one or more receiving samples. Imprinting may be performed using means for applying an electromagnetic field, for example using a device, such as a copper coil or solenoid coil, optionally located inside of an electromagnetically shielded container. The electromagnetic field is applied to the sample for a time period sufficient to produce an EMS signature in the sample, for example for a period of 1 to 24 hrs. Other suitable time periods may be selected based on the nature of the sample, the sample dilution and the physical characteristics of the device or other means for applying the electromagnetic field. Signalized samples produced by this method as well as nucleic acids like DNA amplified from a signalized sample are also contemplated.

[0061] (iii) EMS Recording/Transmission. EMS signals once measured may be recorded on a tangible medium, such as a computer hard drive, a flash drive, DVD, or CD or other known media. They may be transmitted electronically, for example, over the internet, or by any other means that preserves the signal integrity. Recorded or received signals can be amplified and used to transduce EMS into a naïve solution as described above. This aspect of the invention can involve the recording, transducing, storing, and/or transmission of an EMS signature of a nucleic acid, such as that produced after serial dilution of a signalized sample. An EMS signature may be recorded by a suitable electronic device, such as a recorder, computer or computer network. The recorded EMS signature may undergo signal processing or signal transformation for example into a digital or analog signal, be transmitted by a communications device, such as via radio, telephone, modem, or Internet transmission to a receiver, such as a receiving computer, anywhere in the world.

[0062] A stored or transmitted EMS signature is then reconstituted and/or amplified and contacted with a receiving sample to imprint it with the EMS signature and produce nanostructures in the water or dipole solution of the receiving sample. Such a signal may be amplified prior to or after transmission, for example, using a commercial amplifier (e.g., Conrad). The electrical output from the amplifier containing the EMS signature is then applied to an electrically conducting coil (e.g., of copper wire) as described herein in which a plastic tube of pure non-signalized water or other dipole solution has been inserted for a time sufficient for imprinting of the EMS signature, generally for a period of at least one hour.

[0063] The production of EMS is then verified in water dilutions of the signalized water or dipole solution. The positive dilutions can be used for retrieving the DNA by PCR as described above. The DNA is then amplified by cloning and its sequence determined to be 98-100% identical to the initial DNA. This development will be useful for remote diagnosis or use in other telemedicine procedures or protocols.

[0064] The inventors previously discovered that an electromagnetic signal of low frequency (EMS) induced in a water dilution by the DNA of some kinds of bacteria and viruses can be transmitted at a distance into a naive or unsignalized water, aqueous medium or other dipole solution. It has also been discovered that such an EMS corresponding to a particular biomolecule like DNA (i.e., an EMS signature of a particular molecule), can be recorded. This involves recording EMS from DNA fragments obtained by PCR (polymerase chain reaction) with sequence specific primers in an electromagnetic coil. The resulting amplified current is connected to a computer and stored as a file, such as an analog or digital file (e.g., a digital sound file). The recorded EMS can then undergo signal processing, for example a digital sound file can be processed using computer software for storage, transmission, or use.

[0065] DNA may be reconstituted from its EMS signature. For example, the recorded or remotely transmitted EMS signature of a DNA molecule is input into a soundcard and the output from the soundcard is linked to an amplifier. Amplifier output is connected to a transducer solenoid into which an unsignalized water sample is placed. After a certain time, depending on the type of EMS signature, its intensity and the exposure time, the unsignalized water becomes signalized. In other words, the unsignalized water has memorized the EMS signature of the originating DNA molecule. By use of PCR the originating DNA molecule may be retrieved from the water signalized with its EMS signature. Verification of retrieval of the originating DNA sequence from the signalized water or verification of the fidelity of its reproduction can be verified by DNA sequencing.

[0066] Alternatively, prior to retrieval and synthesis of the DNA molecule by PCR, the signalization of the receiving sample with a DNA EMS signature may be determined by detecting the EMS emissions of the signalized sample using dilutions of the signalized water as previously described, e.g., by the device used to record the originating DNA sample's EMS signature in the first place. Only EMS positive dilutions will yield the DNA sequence. The procedure allows the transmission of DNA EMS signatures of medical interest as well as the remote retrieval of the corresponding originating DNA. Such transmission may be made by a medium of choice, for example, a digital signal may be transmitted over the internet or by sending USB keys (e.g., flashdrives) to remote laboratories or medical units.

[0067] (iv) Detection of a Known Nucleic Acid Sequence. Specific molecules known or suspected to be contained in a test sample may be screened using the methods described above. A test sample is diluted and agitated to produce an EMS+ sample and a nucleic acid amplification using specific known primers for the nucleic acid sequence of interest is performed. The test sample may be a sample produced by dilution and agitation or may be produced by tranduction of EMS into a naïve sample. An EMS+ test sample is incubated with primers for a specific nucleic acid sequence and the nucleic acid product by PCR amplification, usually DNA, is recovered. The recovered amplification products may be assayed indicate the presence of the particular nucleic acid in the test sample.

[0068] (v) Identification of an Unknown Nucleic Acid.

[0069] Another embodiment of the invention involves detecting a nucleic acid or nanostructures associated with an unknown nucleic acid in a test sample comprising amplifying a nucleic acid in a test sample using random nucleotide sequence or polynucleotides or primers; diluting and agitating during dilution the amplified nucleic acids in an aqueous solvent; measuring over time a low frequency electromagnetic emission from the diluted amplified nucleic acids; and optionally (i) identifying an EMS signature for amplified nucleic acid or its associated nanostructures by comparing the EMS of the test sample to the EMS of a control sample, and optionally (ii) comparing the results to relevant standard EMS signature(s). This method may further comprise performing a signal analysis of the low frequency electromagnetic emission over time, and/or producing an output, based on the signal analysis. This method may detect a biological molecule, such as a nucleic acid like DNA in a test sample and/or may detect a nanostructure derived from or associated with a nucleic acid such as DNA in the test sample. A suitable dilution of the test sample is selected for use within this method, for example, the test sample can be diluted by a factor of at least 10<4>, 10<5>, 10<6>, 10<7>, 10<8>, or 10<9>.

[0070] The test sample will usually be obtained from subject suffering from or at risk of developing a particular disease, disorder or condition. For example, the test sample can be obtained from a subject having or suspected of having a parasitic or fungal disease or disorder, a subject having or suspected of having a bacterial disease or disorder, a subject having or suspected of having viral disease or disorder, from a subject having or suspected of having had an autoimmune disorder, a subject having or suspected of having Alzheimer's Disease or Parkinson's Disease or any other neurological disease, a subject having or suspected to have a genetic disease or a gene alteration, or a subject having a disease, disorder or condition of unknown or incomplete etiology in comparison with a noninfected subject. For instance, an EMS signature of an HIV gene sequence, such as that of nef or pol, may be detected in a sample in comparison to a sample not containing the HIV gene sequence. Verification of the presence of a gene sequence in a sample may be made by PCR.

[0071] (vi) Devices. Various devices for use in conjunction with the different aspects of the invention are also disclosed. These include:

[0072] A device for producing an EMS signature in an aqueous buffer comprising at least two containers, at least one for an EMS originating sample and at least one for an EMS receiving sample, an electrically conducting coil that can emit a variable frequency ranging from 1 to 20,000 Hz, optionally connected to an external generator of alternating current having a variable frequency from 1 to 20,000 Hz, means for electromagnetic shielding the at least two containers and the electrically conducting coil.

[0073] A device or other means for transmitting at a distance EMS emitted by a biological sample or by nanostructures contained in a sample is also contemplated. Such a device will contain at least two containers, at least one to contain a sample determined to produce EMS characteristic of a DNA or a similar molecule in a first tube (originating sample), and another tube (receiving sample) to receive emitted EMS and contain signalized water produced. The device will contain an electrically conducting coil linked to an external generator of alternating current having a variable frequency from 1 to 20,000 Hz. The device will have shielding means, such as mu metal >=1 mm in thickness, capable of isolating external ambient electromagnetic signals or noise, enclosing a space into which will accommodate the coil and the containers. Any suitable material may be used to make the coil and the elements and design of the coil are selected based on the size of the samples, shielding, and other elements of the apparatus. One example of a coil is a copper coil with the following characteristics: bobbin with internal diameter 50 mm, length 80 mm, R=3.6 ohms, 3 layers of 112 turns of copper wire, field on the axis to the centre 44 Oe/A, and on the edge 25 Oe/A. An example of shielding is a cylinder of [mu] metal having a minimal thickness of 1 mm, closed at both ends in a manner that completely isolates the enclosed containers and coil from the external ambient electromagnetic noise.

[0074] The following Examples describe particular embodiments of the invention, but the invention is not limited to what is described in these Examples.

EXAMPLE 1

Production of Samples Containing an EMS Signature Characteristic of HIV DNA

[0075] Step A:

[0076] Synthesis of DNA by PCR

[0077] A particular DNA sequence is first synthesized by polymerase chain reaction (PCR) on a DNA template, for example, a region of the LTR sequence present in the viral DNA extracted from the plasma of a HIV infected patient or obtained from a purified infectious DNA clone of HIV1 Lai, is amplified by PCR and nested PCR with respectively LTR-derived outer and inner primers.

[0078] Those were chosen to pick up some conserved regions of the LTR, given to several subtypes of HIV1. This amplified DNA was sequenced and found 100% identical to the known sequence of the prototype strain of HIV1 subtype B, HIV1 LAI (3). The resulting amplicon was determined to be 488 bp long and the nested-PCR amplicon to be 104 bp long.

[0079] Filtration and Dilution: A sample of each amplicon is prepared at a concentration of 2 ng/ml in a final volume of 1 ml of pure water that had been previously filtered through a sterile 450 nM Millipore (Millex) filter and then to a 20 nM filter (Whatman, Anotop) to eliminate any contamination by viruses or bacteria. All manipulations are done under sterile atmosphere in a biological safety cabinet.

[0080] The DNA solution is diluted one in 100 (10<-2>) in 2 ml of water and filtered through a 450 nM Millex filter (Millipore) and filtered again through an Anotop filter of porosity size 20 nM (Whatman).

[0081] The resulting DNA filtrate (there is practically no DNA loss through filtration, as the DNA molecules do not bind to the filters), is then diluted serially 1 in 10 (0.1 ml in 0.9 ml of water in an Eppendorf sterile tube of 2 ml from 10<-2 >to 10<-15>.

[0082] A strong vortex agitation was performed at each dilution step for 15 seconds.

[0083] Each dilution in its stoppered plastic tube was placed on a coil under the ambient electromagnetic background at room temperature for 6 seconds; the resulting electric current is amplified 500 times and analyzed in a Sony laptop computer with specific software as previously described. The EMS positive vibrating dilutions (usually between 10<-4 >to 10<-8>) were detected not only by new peaks of frequency, but also quantitatively by the difference in amplitude and intensity of the signals measured in the software, as compared to the same parameters given by the background noise.

[0084] Table 1 shows the role of excitation frequency in inducing EMS from DNA into water. A fragment of LTR DNA (Tar region, 104 base pairs) was amplified by PCR with specific primers from the entire genomic HIV1 LAI DNA cloned in a plasmid (pLAI2). The fragment was purified by electrophoresis on an agarose gel; the DNA band was then cut and extracted with a Qiagen kit. Time of exposure DNA tube and water tube to the exciting frequency was 18 hrs.

[0000]

TABLE 1

Content	Frequency (Hz)	EMS	% over noise	Positive dilutions
LTR DNA 104 bp	2	+	33.3	D6-> D8
Water		-	1.2	
DNA	3	+	39.6	D4-> D7
Water		-	0.5	
DNA	4	+	43.9	D5-> D8
Water		-	1.5	
DNA	5	+	41.6	D5-> D8
Water		-	0	
DNA	6	+	33.5	D5-> D8
Water		-	1	
DNA	7	+	40	D6-> D8
Water		+	43.9	D5-> D8

[0085] Step B:

[0086] Producing a Signalized Sample from the Originating Sample

[0087] Tube 1 containing one of the dilutions found positive for EMS in step A (10<-6>) was placed in the vicinity of an identical tube 2 that had been previously filled with 1 ml of pure water under a separate safety cabinet different from the one utilized in step A for the DNA manipulation. Both tubes were placed inside a copper coil with the following characteristics: bobin with internal diameter 50 mm, length 80 mm, R=3.6 ohms, 3 layers of 112 turns of copper wire, field on the axis to the centre 44 Oe/A, and on the edge 25 Oe/A, linked to an external generator of alternate electric current of variable frequency from 1 to 20,000 Hz.

[0088] The tubes and the coil were enclosed in a cylinder of thick (1 mm) [mu]metal closed at both ends in order to isolate the system from the external ambient electromagnetic noise. A current intensity of 100 mA was applied to the coil, so that no significant heat was generated inside the cylinder.

[0089] The tubes were kept 18 Hrs at room temperature in an oscillating magnetic field strength of 25 Oe/A generated by the coil system. Afterwards, the signalized water of tube 2 is filtered on 450 nM and 20 nM filters and diluted from 10<-2 >to 10<-15>. As a control, the tube 1 was also filtered and diluted in the same way. EMS analysis revealed positive dilutions for EMS, starting at 10<-2 >which is explained if one takes into account that the emitter tube 1 was already at the 10<-6 >dilution (FIG. 1). As shown in Table 1 a minimal frequency of 7 Hz was found necessary and sufficient to induce the EMS in the naïve, unsignalized water filled tube 2. However, the intensity of the EMS signals was sometimes reduced by comparison to those found in tube 1. To determine conditions suitable for EMS transduction, the inventors also varied different parameters of the process. It was determined that the following conditions suppressed EMS emission from naïve tube 2 (receiving sample or sample to be signalized).

[0090] Time of exposure of the two tubes less than 16-18 hrs (Table 2).

[0091] No coil.

[0092] Generator of magnetic field turned off.

[0093] Frequency of excitation<6 Hz.

[0094] No use of DNA in tube 1.

[0095] Tube 2 frozen at -80[deg.] C. overnight and defrosted before recording the EMS.

[0096] Tube 2 heated at 95[deg.] C. for 60 minutes after the overnight exposure.

[0097] Based on the results in Table 1 and on testing of the process conditions and parameters it was concluded that excitation of tube 1 by a magnetic field of low frequency and of very low intensity has allowed the water nanostructures generated by the DNA fragment contained in this tube to be transmitted via waves to tube 2.

[0098] Step C:

[0099] Reconstitution by PCR of the LTR DNA from the Nanostructures in the Receiving or Signalized Sample.

[0100] A sample volume (5 [mu]l) of tube 2-signalized water was added to 45 [mu]l of an amplification mixture in a propylene 200 [mu]l PCR tube (Eppendorf).

[0101] The amplification mixture was composed of (buffer composition) 0.2 mM dNTP's, 10 [mu]M of each specific HIV-1 LTR primer containing the ingredients for synthesizing DNA, either from a positive dilution for EMS or in a lesser dilution, starting with 10<-2 >down to 10<-10>: and using 1 unit of Taq DNA polymerase.

[0102] Once the first cDNA strand is synthesized, cycling of denaturation, annealing and polymerization steps are performed as usually used for the PCR amplification.

[0103] The reaction (35 cycles, T[deg.] annealing 56[deg.] C.) yielded a DNA band of the size (in electrophoresis migration in agarose 1.5%) of the expected 104 bp sequence. This amplicon was then cloned in a bacterial plasmid (Topo Cloning, Invitrogen) which was used to transform bacterial competent cells. Plasmid clones were purified from isolated bacterial transformants and screened for the presence of the 104 bp insert by EcoRI digestion. Positive plasmid clones are then sequenced and the sequence of the insert shown to be 98% to 100% identical (difference of 2 nucleotides) to the original DNA of tube 1.

[0104] The first step of DNA synthesis using the nanostructures as templates can also be achieved by a reverse transcriptase (RT) and other more classical DNA polymerase, at lower temperature (42[deg.] C. for example for the reverse transcription step). HIV1 LTR DNA D6 (EMS positive) dilution was used as emitter using excitation frequency of 7 Hz during 18 hours in the apparatus described in FIG. 1, and placed close to the water receiver Tube 2. Like the latter, it was then diluted at 10<-2>, refiltered by 450 nM and 20 nM filters and diluted to 10<-15>.

[0105] Each dilution was then amplified by PCR for 35 cycles. Note the DNA bands detected at dilutions D2, (FD2), D3, D4, and D5. It has to be noted that the synthesis of the DNA LTR band is obtained in high water dilutions (up to 10<-9>) of the tube 2 containing the signalized water, indicating the transmission of the DNA information from tube to tube, in the presence of the ambient electromagnetic background. The same phenomenon was also observed in high dilutions of tube 1, indicating the synthesis of DNA at dilutions containing no DNA molecules.

[0106] This PCR technology can be applied to the detection of nanostructures in body fluid (plasma, urine) apparently devoid of the microorganisms from which they originate. In all cases, it is necessary to use mechanical agitation (vortex) at each water dilution in addition to the ambient or controlled electromagnetic background.

[0107] Table 2 shows the role of time of exposure to the 7 Hz frequency on EMS transmission from DNA to water. These results used the DNA LTR preparation as used for procedures reported in Table 1.

[0000]

TABLE 2

Content	Time of exposure (hr)	EMS	% over noise	Positive dilutions
Control DNA tube	2	+	57.3	D4-> D8
Water	2	-	0	
Water	4	-	0	
Water	6	-	0	
Water	8	+-	6.4	D4-> D8
Water	16	+	13.4	D5-> D8
Control DNA tube	16	+	63	D4-> D8

[0108] As shown above EMS were detected in the receiving sample after an exposure time of 8 or 16 hrs when the originating sample exhibited positive EMS at dilutions of D4 to D8 (10<-4 >to 10<-8>). No EMS was detected in water exposed for less than 8 hrs.

EXAMPLE 2

Identification of Unknown DNA Using Random Primers

[0109] Another aspect of the invention is directed to a general procedure for the identification of any unknown DNA sequence (or polynucleotide sequence) capable of producing EMS in biological fluids. The principle is shown by FIG. 3. The transmission of EMS in water allows the selective transmission of only the DNA sequences that were emitting the EMS under the induction conditions. The PCR method uses a combination of random and Tag primers. The random primer associated with the Tag has the following formula 5'-GGACTGACGAATTCCAGTGACTNNNNNNNN (SEQ ID NO: 1) in which are made all possible combinations of 8 nucleotides for the 4 possible bases (65,536). A detailed procedure is described below.

[0110] 1) DNA is purified from EDTA-collected human plasma extracted by the kit, QiaAMP, (Qiagen).

[0111] 2) The purified DNA samples are filtered through 0.45 and 0.1 [mu]m filters and then diluted to FD2-FD15 for analysis of EMS. FD2 refers to a filtered dilution of 1:100 or 10<-2>.

[0112] 3) The filtered and diluted samples are used to signalize water (molecular biology grade, 5Prime, 20 nm-filtered) with a dilution EMS+ of a patient DNA sample under an oscillating magnetic field of 7 Hz, 4V (coil in mu-metal) for 18 hours.

[0113] 4) Each EMS+ sample used is filtered, vortexed and diluted (FD2-FD5) the signalized water sample and proceed to EMS analysis.

[0114] 5) The samples of signalized water (EMS+), starting with FD2 are used as template for PCR amplification using random and Tag primers, following the protocol described below:

[0115] A 49 [mu]l PCR amplification mix containing 1* Advanced Taq buffer with Mg<2+> (available from 5Prime Co.), 200 [mu]M dNTPs, 20 nM of designed random primer Tag8N (SEQ ID NO: 1):

[0000]
(SEQ ID NO: 2)
(5'-GGACTGACGAATTCCAGTGACTNNNNNNNN)

[0116] 20 [mu]l of vortexed FD2 signalized water template, and 1 unit of Taq DNA polymerase (available from 5Prime Co.) is incubated stepwise at 8[deg.] C., 15[deg.] C., 20[deg.] C., 25[deg.] C., 30[deg.] C., 36[deg.] C., 42[deg.] C., and 46[deg.] C. for 2 min at each temperature to allow annealing of the random portion of the primer. An elongation step at 68[deg.] C. for 2-15 min was performed to allow synthesis of DNA, followed by a denaturation step at 95[deg.] C. for 3 min. One [mu]l of the designed primer Tag-ONLY (5'-GGACTGACGAATTCCAGTGACT) (SEQ ID NO: 3) is added to the mixture at a final concentration of 200 nM. The resulting sample is subjected to 40 cycles of amplification (95[deg.] C./30 s, 59[deg.] C./30 s, and 70[deg.] C./2 min), followed by an incubation at 70[deg.] C. for 10 min. PCR-amplified samples are subjected to electrophoresis in 1.3% agarose gel and stained with ethidium bromide to allow visualization of amplified DNA bands under UV light.

[0117] 6) If needed (if faint or no DNA bands a-re detected), sample can be reamplified by PCR using only the primer

Tag-ONLY, following the reamplification protocol described below:

[0118] A 50 [mu]l PCR amplification mix containing 1* Hot Start Taq buffer with Mg<2+> (available from 5Prime Co.), 200 [mu]M dNTPs, 200 nM of designed primer Tag-ONLY (5'-GGACTGACGAATTCCAGTGACT) (SEQ ID NO: 3), 1-10 [mu]l of PCR-amplified sample as template, and 1 unit of Hot Taq DNA polymerase (available from 5Prime Co.) is denatured at 95[deg.] C. for 3 min and subjected to 25-40 cycles of amplification (95[deg.] C./30 s, 59[deg.] C./30 s, and 70[deg.] C./2 min), followed by an incubation at 70[deg.] C. for 10 min.

[0119] 7) Isolation, purification and cloning of amplicons in pCR2.1-TOPO (InVitrogen) vector, followed by transformation of competent Escherichia coli cells, and screening for positive clones.

[0120] 8) DNA sequencing of amplicons using M13 universal primers (Eurofins MWG GmbH, Germany) and BLAST of the resulting sequences.

[0121] Application to a patient suffering from chronic Lyme disease:

[0122] A D9 (10<-9>) dilution of DNA extracted from the plasma of a patient suffering from chronic Lyme disease was transduced into water at an excitation frequency of 7 Hz for 18 hrs. PCR was performed on the water sample after transduction with Tag8N primers followed by a second PCR with Tag primers only. The PCR DNA products were resolved on agarose gels by electrophoresis and are shown in FIG. 4. As shown at the left, results obtained when the tube of D9 DNA and the naive tube of water are placed side-by-side. At right, results obtained when the two tubes were placed at a distance of 4 cm from each other.

[0123] Dw denotes control, naïve, unsignalized water.

[0124] Dw vor: denotes control naïve, unsignalized water agitated with a vortex.

[0125] D0: water that was transduced but not diluted.

[0126] D2 NF: same as D0 but diluted by 1:100 (D2).

[0127] D2 same as D2 NF, but filtered.

[0128] D3, D4, D5 represent further serial dilutions of D2 to factors of 1:1,000 (D3); 1:10,000 (D4) and 1:100,000 (D5). All serial dilutions were vortexed between each 1:10 dilution.

EXAMPLE 3

Recording and Transduction of EMS Signatures of HIV and Borrelia Burgdorferi

[0129] EMS signatures of HIV DNA and Borrelia DNA sequences are recorded and transduced as described below.

[0130] Step 1: Preparation of DNAs

[0131] 1. A fragment of HIV DNA taken from its long terminal repeat (LTR) sequence present in the viral DNA extracted from the plasma of a HIV-infected patient or obtained from a purified infectious DNA clone of HIV1 Lai, is amplified by PCR (487 base pairs) and nested PCR (104 base pairs) using specific primers: TR InS 5'-GCCTGTACTGGGTCTCT (SEQ ID NO: 4) and LTR InAS 5'-AAGCACTCAAGGCAAGCTTTA (SEQ ID NO: 5). A longer variant (300 bp) is obtained using the following primer: 5'-TGTTAGAGTGGAGGTTTGACA (SEQ ID NO: 6) in conjunction with the above primer InAS.

[0132] 2. A DNA sequence from Borrelia Burgdorferi, the agent of Lyme disease, is amplified by PCR (907 base pairs) and nested PCR (499 base pairs) with respectively Borrelia 16S outer and inner primers. Inner BORR16S inS 5'-CAATCYGGACTGAGACCTGC (SEQ ID NO: 7) and BORR16S inAS 5'-ACGCTGTAAACGATGCACAC (SEQ ID NO: 8). A shorter variant of 395 bp is obtained by using the following primer: 5'-GACGTCATCCTCACCTTCCT (SEQ ID NO: 9) in conjunction with the above primer inAS.

[0133] Step 2: Signal Recording

[0134] The resulting amplicons 104 bp and 300 bp for LTR and 499 bp and 395 bp for Borrelia were prepared at a concentration of 2 ng/ml in a final volume of 1 ml of DNAse/RNAse-free distilled water. The samples were read on an electromagnetic coil, connected to a Sound Blaster card (Creative Labs) itself connected to a microcomputer, (preferably Sony VGN-CS31) preferentially powered by its 12 volt battery. Each emission is recorded for 6 seconds, amplified 500 times and the digital file is saved, for example under the form of a sound file with the .wav format. This file can later undergo digital processing, by a specific software, Matlab (Mathworks), as for example digital amplification for calibrating the signal level, filtering for eliminating unwanted frequencies, or be analyzed by transformation into its spectrum by a discrete Fourier transform, preferably by the algorithm of FFT "Fast Fourier Transform".

[0135] Step 3: Signal Transduction in Water:

[0136] For transduction, the digital signal was converted by the digital/analog converter of the sound card into an analog signal. The output of the sound card of the microcomputer was linked to the input of a commercial amplifier (Kool Sound SX-250, www._conrad.com) having the following characteristics: passband from 10 Hz to 20 kHz, gain 1 to 20, input sensitivity 250 mV, output power RMS 140 W under 8 ohms.

[0137] The output of the amplifier was connected to a transducer solenoid which has the following characteristics: the bobbin has a length of 120 mm, an internal diameter of 25 mm, an external diameter of 28 mm, with 3 layers of 631 spirals of copper wire of 0.5 mm diameter and a resistance of 8 ohms, field on the axis to the centre 44 Oe/A, and on the edge 25 Oe/A. A measurement of 4.4 milliTesla (mT) was obtained when current, voltage and resistance were respectively, 100 mA, 4V and 8 ohms.

[0138] 50 ml of DNAse/RNAse-free distilled water (5-Prime Ref 2500010) are filtered first through a sterile 450 nM filter (Millex, Millipore, Cat N[deg.] SLHV033RS) and then to a 20 nM filter (Whatman, Anotop 25, Cat N[deg.] 6809-2002). For transduction, 1 ml of this filtered water in a Eppendorf sterile tube of 1.5 ml was placed at the center of the solenoid, itself installed at room temperature on an isolated (non metal) working bench. Alternatively, a sterile tube of 15 ml (Falcon-Becton Dickinson), filled with the filtered water can be used instead of the 1.5 ml Eppendorf tube.

[0139] The modulated electric current produced by the amplifier was applied to the transducer coil for 1 hr at the tension of 4 Volts. A current intensity of 100 mA was applied to the coil, so that no significant heat was generated inside the cylinder.

[0140] Step 4: Reconstitution by PCR of the DNA from the Signalized Water.

[0141] The water which has received the recorded specific signal is called "signalized water". The signalized water (kept in the same tube) was first agitated by strong vortex for 15 seconds at room temperature and then diluted 1/100 in non signalized DNAse/RNAse-free distilled water (30 [mu]l/3 ml). 1 ml was kept for control (NF, nonfiltered), the 2 mls remaining of signalized water were filtered through a sterile 450 nM filter and then through a 100 nM (Millex, Millipore, Cat N[deg.] SLVV033RS) for Borrelia DNA or 20 nM filter (Whatman, notop25) for HIV DNA. The filtrate was then diluted serially 1 in 10 (0.1 ml in 0.9 ml of DNAse/RNAse-free distilled water) in a Eppendorf sterile tube of 1.5 ml from 10<-2 >to 10<-15 >(D2 to D15). A strong vortex agitation was performed at each dilution step for 15 seconds. 5 [mu]l of each dilution is added to 45 [mu]l of the mix.

[0142] 1. Preparation of the mix for HIV LTR: The PCR mixture (50 [mu]l) contained 37.4 [mu]l of DNAse/RNAse-Free distilled water, 5 [mu]l of 10* Taq PCR buffer, 0.4 [mu]l of 25 mM dNTPs, 1 [mu]l of 50 [mu]M each appropriate primer Inner [LTR InS (5'-GCCTGTACTGGGTCTCT) (SEQ ID NO: 10) and LTR InAS (5'-AAGCACTCAAGGCAAGCTTTA) (SEQ ID NO: 11)], 0.2 [mu]l of 5 U/[mu]l Taq DNA Polymerase and 5 [mu]l of each dilution. The PCR was performed with the mastercycler ep (Eppendorf). The PCR mixtures were pre-heated at 68[deg.] C. for 3 min (elongation step), followed by 40 PCR cycles of amplification (95[deg.] C. for 30 s; 56[deg.] C. for 30 s; 70[deg.] C. for 30 sec). A final extension step was performed at 70[deg.] C. for 10 min.

[0143] 2. Preparation of the mix for Borrelia: The PCR mixture (50 [mu]l) contained 37.4 [mu]l of DNAse/RNAse-Free distilled water, 5 [mu]l of 10* Taq PCR buffer, 0.4 [mu]l of 25 mM dNTPs, 1 [mu]l of 50 [mu]M each appropriate primer Inner [BORR16S inS (5'-CAATCYGGACTGAGACCTGC) (SEQ ID NO: 7) and BORR16S inAS (5'-ACGCTGTAAACGATGCACAC) (SEQ ID NO: 8)], 0.2 [mu]l of 5 U/[mu]l Taq DNA polymerase and 5 [mu]l of each dilution. The PCR was performed with the mastercycler ep (Eppendorf). The PCR mixtures were pre-heated at 68[deg.] C. for 3 min (elongation step), followed by 40 PCR cycles of amplification (95[deg.] C. for 30 s; 61[deg.] C. for 30 s; 70[deg.] C. for 1 min). A final extension step was performed at 70[deg.] C. for 10 min.

[0144] Electrophoresis of the PCR products in 1.5% agarose gel: A band of 104 bp for HIV LTR and a band of 499 bp Borrelia DNA should be detected at several dilutions.

[0145] 3. Sequencing: The DNA bands are cut and DNA is extracted using a Qiagen kit which also describes classical conditions for cloning in E. coli. The amplified specific DNA is then sequenced to show its identity to the original DNA.

Method of Detecting Microorganisms with a Specimen

Abstract -- This invention concerns a process for preparing reagents intended for a microorganism detection test and notably an infection in humans or animals, wherein the following steps are included: a) Centrifuging a biological or artificial liquid medium containing a selected specific microorganism; b) Filtrating the supernatant obtained in step (a); c) Preparing a series of diluted samples corresponding to increasing dilutions of the filtrate obtained in step (b), down to a filtrate dilution of at least a factor of 10-15; d) Submitting said diluted samples obtained in step (c) to an electrical, magnetic, and/or electromagnetic exciting field; e) Analyzing the electrical signals detected using a solenoid, as well as digitally recording said electrical signal after analog/digital conversion of said signal; f) Selecting diluted samples with which the characteristic electrical signals were obtained in (e), i.e. signals whose amplitude is at least 1.5 times greater than background noise emitted by water and/or presenting a frequency displacement towards higher values; g) Placing the diluted samples selected in step (f) into protective enclosures, which are protecting said dilutions against external electromagnetic fields; h) Distributing one of the aforesaid diluted samples from step (g), volume by volume, into two tubes, T1 and T2, tube T1 remaining in a protective enclosure protecting diluted samples from external electromagnetic field interferences, and acting as a reference solution, tube T2 being also placed in a protective enclosure, and subjected subsequently to the presence or contact of a sample suspected to contain said selected specific microorganism.

Description

[0001] This invention has for object to reveal latent infections in humans and animals, by showing inhibition, through the examinee, of electromagnetic signals generated by a microorganism.

[0002] From the works by Dr. Jacques BENVENISTE and from patent application WO 00/17637, it has been known how to record and digitalize, after analog-to-digital conversion using a computer sound board, an electrical signal characteristic of a molecule possessing a biological activity.

[0003] Also known in prior art (WO 09417406) is a process and a device used to transmit biological activity from a first matter, so-called carrier, to a second matter, so-called target, the latter exempted of any traces from said carrier and physically separate from it, and the target not presenting initially the aforementioned biological activity. The method consists in (i) exposing the matter carrying the biological activity of interest to an electrical or electromagnetic signal sensor, (ii) amplifying said electromagnetic or electrical signals characteristic of the emitted biological activity feature, then (iii) exposing the target matter to an emitter of electrical or electromagnetic signals, said emitter being connected to aforesaid sensor through a transmission and amplification circuit, in order to transmit the signal characteristic of biological activity to said target.

[0004] In a previous French patent application 05/12686 filed on Dec. 14, 2005, not yet issued to this day, the inventor of this invention was describing a process for characterizing biochemical elements presenting a biological activity, microorganisms in this case, by analyzing low frequency electromagnetic signals, said process bringing improvements to prior art techniques. Said process also relates to biological analysis consisting in recording the electromagnetic or electrical "signatures" corresponding to known biochemical elements, and to compare such pre-recorded "signatures" to that of a biochemical element to be characterized. Said process implicates filtration and dilution steps in order to eliminate microorganisms and cells present within the original sample, the highest dilutions generating the most electrical or electromagnetic signals whereas the least diluted samples don't provide, most of the time, any electrical or electromagnetic signals. The inventor also showed that microorganisms of different nature, such as bacteria and viruses, produce "nanostructures" that persist in aqueous solutions, and that these very "nanostructures" are emitting electromagnetic signals. Said "nanostructures" behaves like polymers of a size less than 0.02 [mu]m for viruses, and less than 0.1/[mu]m for classic size bacteria, and present a density ranging from 1.12 and 1.30 g/ml.

[0005] The process described in this application is based on the astonishing observation that in absence of physical contact, the mere vicinity of a closed tube containing a sample of a bacterial or viral filtrate, little diluted and negative with regard to electrical or electromagnetic emitting signals, inhibits the signals produced by a more diluted sample of the same filtrate, initially positive with regard to electrical or electromagnetic signal emission. In this application, such inhibition will be indistinctly called "inhibitory effect" or "negativing effect". In the same way, in this application, to "inhibit" and "negativate" will be used indistinctly and have a similar meaning. This observation led the inventor to search for the same inhibitory phenomenon from an infected human being. It has been observed, in a patient suffering from an auto-immune microvascularitis of infectious origin, that the diluted samples of his plasma had an inhibitory effect on dilute filtrates of E. coli emitting electromagnetic signals (hereafter EMS), suggesting that the patient was suffering from a chronic infection by this or a related germ. It was also shown that the patient suffering from microvascularitis, as mentioned in the previous example, himself inhibits the EMS emitted by his filtered and diluted plasma, and also inhibits the EMS emitted by a filtered and diluted sample of E. coli culture present in a closed tube. In this case, a 5 minutes contact of a positive dilution in the patient's hand, or 10 minutes at a distance of up to 50 cm, are sufficient to observe said inhibitory effect.

[0006] Said inhibitory power thus involves both the emitting structures from one own plasma, and those of a specific bacterial germ, which could thus be used as a universal identification system.

[0007] The invention may therefore enable to determine a bacterial or viral origin in illnesses where such germs have not been identified.

[0008] A first object of the invention concerns a method for preparing reagents to be used in a test for detecting a microorganism and notably an infection in humans or animals. According to its most general acception, the method includes the following steps:

[0000] a) Centrifuging a biological or artificial liquid medium containing a selected specific microorganism;

b) Filtrating the supernatant obtained at step (a);

c) Preparing a series of diluted samples corresponding to increasing dilutions of the filtrate obtained in step (b), down to a filtrate dilution factor of at least 10<-15>;

d) Submitting the diluted samples obtained in step (c) to an electrical, magnetic and/or electromagnetic exciting field;

e) Analyzing the electrical signals detected using a solenoid and recording digitally aforesaid electrical signal, after analog/digital conversion of aforesaid signal;

f) Selecting diluted samples from which the characteristic electrical signals were obtained in (e), by characteristic signals one means signals whose amplitude is at least 1.5 times greater than background noise emitted by water, and/or presenting a frequency displacement towards higher values;

g) Introducing the diluted samples selected in step (f) in protective enclosures, which protect said dilutions from very low frequency external electromagnetic fields;

h) Distributing one of aforesaid diluted samples from step (g), volume by volume, in two tubes, T1 and T2, with T1 remaining in a protective enclosure protecting said diluted samples from external electromagnetic field interferences, said tube T1 acting as a reference solution, while tube T2, also placed in a protective enclosure, is subsequently being subjected to the presence or contact of a sample suspected of containing said selected specific microorganism.

[0009] By "a sample to be tested for presence or absence of aforesaid selected specific microorganism" one means: (i) a human or animal individual suspected to be infected by aforesaid selected specific microorganism, or (ii) a biological specimen or a biological or artificial fluid suspected of containing said selected specific microorganism, or (iii) a food component, a cosmetic, or a pharmaceutical composition susceptible to contain said selected specific microorganism.

[0010] By biological fluids, one means any human or animal fluid, e.g. blood, urine, various secretions. By artificial fluid, one means any reconstituted fluid for growing microorganisms, e.g. various culture media for bacteria, yeasts, and molds, and culture media for cells infected by a virus.

[0011] Another object of the invention concerns a system for detecting a microorganism within a sample. This system includes:

[0000] a) A tube T1 containing a reference sample emitting characteristic electrical signals, by characteristic signals one means signals whose amplitude is at least 1.5 times greater than background noise emitted by water, and/or presenting a frequency displacement towards higher values;

b) A tube T2 containing a sample emitting characteristic electromagnetic signal, said sample being identical to that contained in tube T1;

c) A protective enclosure for protecting tubes T1 and T2 against very low frequency external electromagnetic fields;

d) A tube T3 containing a control solution not presenting electromagnetic signal emission;

e) An equipment for receiving electromagnetic signals.

[0012] During detection, tube T2 will be subjected to the presence or contact of sample X to be tested for presence or absence of a selected specific microorganism.

[0013] Another object of the invention concerns a method for detecting a microorganism within a sample, characterized in that said method consists of the following steps:

[0000] a) A sample X, for which the presence of a suspected microorganism, e.g. E. coli, is to be established, is exposed to a sample as obtained after step (f) of the process according to one of claims 1 to 3, said sample obtained after step (f) being a dilution of a culture or biological medium filtrate containing said microorganism suspected to be present in sample X;

b) Comparing the electromagnetic signal emitted by sample X exposed to said sample obtained after step (f), obtained in step (a), with the electromagnetic signal emitted by an aliquot of the same sample obtained after step (f) and not submitted to sample X.

[0014] By "a sample X", one means (i) a human individual or animal suspected of being infected by aforesaid selected specific microorganism, or (ii) a biological specimen, or a biological or artificial fluid, suspected to contain said selected specific microorganism, or (iii) a food component, cosmetic, or pharmaceutical composition susceptible to contain said selected specific microorganism.

[0015] The methods according to the invention enable (i) to prepare reagents intended for a test to detect microorganisms implicated in chronic illnesses, and/or intended to detect systemic latent infections under circumstances where a quick and non invasive response is required, as it is in the case of e.g. avian flu virus detection, (ii) the identification of an infection in humans or animals.

[0016] Once the responsible microorganism identified, it is possible to confirm the presence of that germ using supersensitive PCR with specific oligonucleotidic promoters from such microorganism.

[0017] The invention shall be better understood by reading the following description, presenting in a non restrictive way examples of process embodiment according to the invention.

[0018] The figures in annex correspond to non restrictive examples of embodiment.

EXAMPLE 1

A Lightly Dilute Bacterial Culture, not Emitting Electromagnetic Signals, "Negates" the Electromagnetic Signals Emitted by a Strong Dilution from the Same Culture

1) Sample Preparation

[0019] An Escherichia coli (E. coli) bacteria culture in LB (Luria broth) medium is centrifuged at 8000 rpm for 15 minutes in order to eliminate the cells. The bacterial supernatant is then filtered on a 0.45 [mu]m porosity PEVD Millipore filter, and the filtrate is then again filtered on a 0.1 [mu]m porosity Millipore filter.

[0020] From the resulting E. coli culture filtrate, which is completely sterile, one prepares a series of samples by diluting the filtrate from 10 to 10 into water down to 10<-15 >for injectable preparation. The successive dilutions are strongly agitated with a vortex for 15 seconds between each dilution.

[0021] The diluted samples are distributed in 1.5 ml Eppendorf conic plastic tubes. The fluid volume is in general of 1 milliliter.

[0000] 2) Selection of Diluted Samples Generating Electromagnetic signals.

[0022] Each dilute sample is tested for emission of low frequency electromagnetic signals.

[0023] The procedure for detecting EMS includes a step aimed at transforming the electromagnetic field from various diluted samples into one signal, namely an electrical signal, using a solenoid for capturing said electromagnetic field.

[0024] The transformation of the electromagnetic field coming from the diluted sample analyzed into an electrical signal is done as follows:

[0000] (i) Submitting the dilute sample being checked to an electrical, magnetic and/or electromagnetic exciting field;

(ii) Analyzing the electrical signals detected using a solenoid and digitally recording aforesaid electrical signal after analog/digital conversion of said signal;

(iii) Selecting the diluted samples generating characteristic electrical signals, by 'characteristic' one means signals whose amplitude is at least 1.5 times greater than background noise signals emitted by water and/or presenting a frequency displacement towards higher values, and placing them in Mumétal(R) protective enclosures for protecting said diluted samples against external electromagnetic field interferences.

[0025] Signal detection is carried out using the equipment schematically represented in FIG. 1. The equipment consists of a solenoid reading cell (1) sensitive from 0 to 20000 hertz, placed on a table made of insulating material. Said solenoid used in step (ii) includes a winding comprising a soft iron core. Said winding has an impedance of 300 ohms, an inside diameter of 6 mm, an outside diameter of 16 mm, and a length of 6 mm. The magnetic soft iron core is placed in contact with the external walls of the tube containing the dilution to be analyzed.

[0026] The diluted samples to be read are distributed in 1.5 ml Eppendorf (trade mark) conic plastic tubes (2). The fluid volume is in general of 1 milliliter.

[0027] Characteristic electrical signal acquisition is performed for a preset duration, i.e. ranging from 1 to 60s. In this example, each sample is read twice successively for 6 seconds.

[0028] The electrical signals delivered by the solenoid are amplified and converted into analog-digital signals using a signal acquisition board (sound card) (4) including a computer-built-in analog-to-digital converter (3). Said analog-to-digital converter has twice the sampling rate of the maximal frequency that one wants to digitalize, e.g. 44 kHz.

[0029] The digital file corresponding to said converted electrical signal is saved on a mass storage, e.g. as a WAV format audio file.

[0030] For processing the characteristic electrical signal, one uses e.g. Matlabs and SigViews (trademarks) software. The recorded digital file may possibly undergo digital processing, i.e. digital amplification for calibrating the signal level, filtering for eliminating undesired frequencies, calculating spectral power distribution (SPD), then such spectral power is truncated, e.g. only keeping frequency bands from 140 Hz to 20 kHz (Matlab), or is transformed in frequency components by Fourier transform (SigView).

3) Evaluating the Inhibitory Activity of a Non-Emitting Low Dilution on the Emission of Electromagnetic Signals Generated by an Active Dilution.

[0031] The diluted samples presenting characteristic electrical signals are samples diluted to 10<-8>, 10<-9>, 10<-10>. The 10<-2 >to 10<-6 >dilutions are negative (FIG. 2).

[0032] A closed tube containing a 10<-3 >dilution aliquot of E. coli is placed side by side with a closed tube containing a 10<-8 >diluted sample aliquot of E. coli, in an enclosure surrounded by a Mumétal(R) magnetic shield, and left 24 hours at room temperature. In parallel, a control series is realized. This control series consists of one tube containing a 10<-3 >diluted sample aliquot of E. coli, and of another containing a 10<-8 >diluted sample aliquot of E. coli that is processed in the same way, but in separate Mumétal(R) enclosures distant from one another. The placement in a Mumétal(R) enclosure eliminates very low active frequencies (5 to 100 Hertz) but not higher frequencies that could come from ambient electromagnetic noise.

[0033] After 24 hours, the tubes containing the diluted samples are again analyzed as describes above, revealing that the tube containing a 10<-8 >diluted sample aliquot and coupled to the tube containing a 10<-3 >diluted sample aliquot, no longer emits any electromagnetic signals, or much weaker ones. On the other hand, the control series tubes remained identical; the tube containing a 10<-8 >diluted sample aliquot protected from contact with the tube containing a 10<-3 >diluted sample aliquot remained positive for electromagnetic signal emission.

[0034] An important particularity of the invention is that the observed negating effect is specific, i.e. the lightly diluted, non-emitting sample and the greatly diluted electromagnetic signal-emitting sample must come from the same microorganism species.

[0035] Thus, the diluted E. coli-emitting samples are only "negated" by a weakly diluted non-emitting E. coli sample, but not by a lightly diluted non-emitting Streptococcus or Staphylococcus sample. Similarly, a diluted emitting Staphylococcus sample is only "negated" by a lightly diluted non-emitting sample of Staphylococcus and not by a lightly diluted non-emitting sample of Streptococcus or E. coli.

EXAMPLE 2

Quick and Non-Invasive Method for Detecting Infections in Humans and Animals

1) Preparations of Biological and Artificial Fluid Samples Containing Microorganisms.

[0036] A blood sample, collected with anticoagulant, preferably heparin, from a patient suffering from a neurological pathology consecutive to a bacterial infection, and an Escherichia coli (E. coli) bacteria K1 culture in suspension in LB (Luria broth) medium are centrifuged in order to eliminate the cells. The bacterial supernatant and/or the plasma collected are then diluted to 10<-2 >in RPMI medium. The solutions are filtered on 0.45[mu] Millipore PEVD filter, then the filtrate is again filtered on 0.02 [mu]m Whatman or 0.1 [mu]m Millipore filter.

[0037] From the plasma filtrates of infected individual and from the E. coli K1 culture, one prepares a series of diluted samples corresponding to increasing dilution levels, up to 10<-15>, in 10 to 10 dilutions in water for injectable preparation under laminar flow hood. The successive dilutions are strongly agitated with a vortex for 15 seconds between each dilution.

[0038] The diluted samples are then distributed in 1.5 ml conic Eppendorf plastic tubes. The fluid volume is in general of 1 milliliter.

2) Selection of Diluted Samples Generating Electromagnetic Signals.

[0039] The selection of the diluted samples emitting characteristic signals, signals whose amplitude is at least 1.5 times greater than the background noise signals and/or are of a frequency higher than background noise, is realized identically to what is described above in example 1, chapter 2. The method described as well as the material are identical to what is described above. Thus, the method includes a step for transforming the electromagnetic field from different dilutions into a signal, namely an electrical signal, by means of a solenoid capturing said electromagnetic field.

[0040] The transformation of the electromagnetic field from the analyzed dilution into an electrical signal is done by:

(i) Submitting the diluted sample being checked to an electrical, magnetic and/or electromagnetic exciting field;

(ii) Analyzing the electrical signals detected using a solenoid, and digitally recording said electrical signal after analog/digital conversion of aforesaid signal;

(iii) Selecting the diluted samples presenting characteristic electrical signals, by 'characteristic' one means signals whose amplitude is at least 1.5 times greater than background noise signals emitted by water, and/or presenting a frequency displacement towards higher values, and placing them in protective enclosures for protecting said diluted samples against external electromagnetic field interferences.

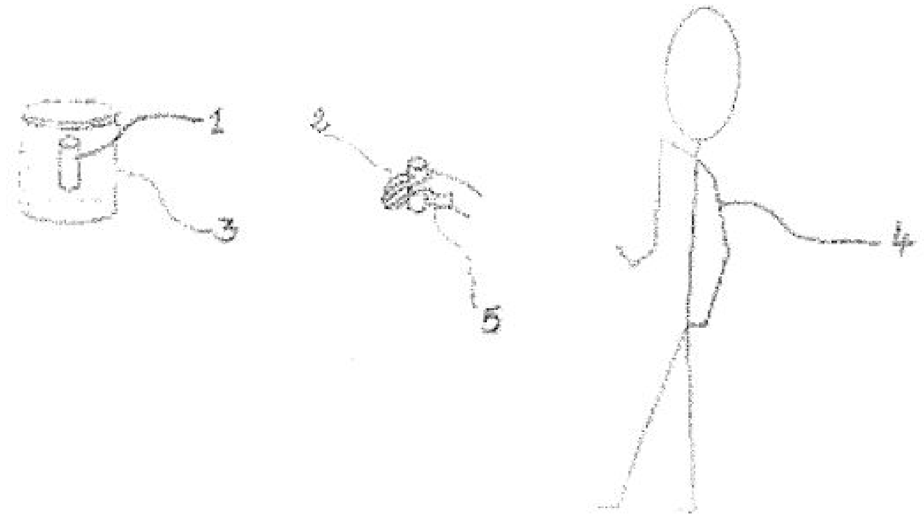
3) Evaluating an Infected Individual's Inhibitory Activity on the Electromagnetic Signal Emission Generated by a Microorganism.

[0044] The diluted samples selected at the previous step (item (iii)), from the plasma filtrate of the infected individual, from E. coli culture filtrate, i.e. the dilutions of filtered sample presenting a characteristic electrical signal, are distributed in Eppendorfs plastic tubes, at a rate of 1 ml per tube, and stored at +4[deg.] C. The diluted EMS emitting samples distributed in aliquots are protected from external influences by being placed in an enclosure protected from electromagnetic fields. Preferably, the enclosure is surrounded with a magnetic shield made of Mumétal(R), isolating the enclosure from very low frequency parasitic fields coming from the surroundings.

[0045] One of the diluted EMS emitting samples from the plasma filtrate of the infected individual, from E. coli culture filtrate, is distributed volume to volume in two tubes, T1 and T2, with T1 remaining in a protective enclosure protecting said diluted samples from external electromagnetic field interferences, that tube will act as reference solution; tube T2 will be subsequently subjected to the patient and is also placed in a protective enclosure.

[0046] Said protective enclosure being preferably surrounded with a Mumétal(R) shield.

[0047] **FIG. 2** represents schematically the steps to take when searching for the inhibitory effect. The search of the inhibitory effect is realized as follows:



a) Tube T1, containing the reference solution, remains in an enclosure (3) surrounded by a Mumétal(R) magnetic shield, said tube T1 is thus protected from potential changes of the individual to be examined (4), whereas tube T2 is submitted to the influence of the infected individual to be examined (4) whose plasma present in tubes T1 and T2 comes from, said individual holds T2 in his/her hand (5) for a set period of time, e.g. 5 minutes;

b) Tube T2 is placed in an electromagnetic signal reception equipment, preferably a reading solenoid cell as described previously in chapter 2 of this example;

c) Electrical signals are then amplified, processed, converted into analog-digital signals as previously described in chapter 2;

d) Said analog-digital signals are possibly decomposed in harmonics by Fourrier transform.

[0052] The signals corresponding to tube T1 and those corresponding to tube T2, as well as the signals corresponding to water containing tube T3 (background noises) are compared.

[0053] The following figures represent the results obtained in the case where the active dilution comes from the examined infected individual plasma:

FIG. 3 represents a histogram in three dimensions (Matlab) of the electrical signals detected by the solenoid with tube T3 present (background noises);

[0060] The analysis by 3 dimensions histogram, respectively for background noise (FIG. 3) and for the signal obtained with tube T1 present and containing the EMS emitting reference solution (FIG. 4), shows a displacement towards higher frequencies. On the other hand, when analyzing tube T2 containing the solution submitted to the influence of the individual to be examined (FIG. 5), no displacement toward higher frequencies is noted; the 3D histogram representing the signals of tube T2 is analogous to that obtained for background noise.

[0061] Fourier analysis of the positive frequencies generated by tube 1 (FIG. 7) revealed peaks at various frequencies. By decreasing order of signal intensity, the following frequencies presented signals: 1000, 2000, 3000, 4100, 5100 and 5500. On the other hand, Fourier analysis of tube T2 reveals results analogous to those obtained by background noise analysis: no significant peak was observed for background noise or for tube T2.

[0062] In conclusion, these analyses enable to deduct that the individual examined has a capacity for inhibiting electromagnetic signals emitted by a dilution of his/her own plasma.

[0063] Analogous results were obtained with the reference solution, derived from K1 E. coli.

[0064] Therefore, this inhibitory capacity concerns not only his/her own plasma but also E. coli emitting structures, suggesting that the individual is infected by an agent producing nanostructures close to those of E. coli.

Lucid Dreaming/Induction Techniques

This page describes a number of lucid dream induction techniques. It is recommended that you be able to recall *at least* one dream per night in order to maximize the effectiveness of these methods.

Certain elements are common to many of the lucidity-inducing techniques discussed later in this chapter. To better understand these techniques, these common components will be discussed first.

Sleep Interruption

An element shared by many of the techniques is sleep interruption. Sleep interruption is the process of purposefully awakening during your normal sleep period and falling asleep a short time later (10–60 minutes). This can be easily done by using a relatively quiet alarm clock to bring you to consciousness without fully waking you. If you find yourself resetting the clock in your sleep, it can be placed on the other side of the room, forcing you to get out of bed to turn it off. Other biorhythm-based options involve drinking lots of fluid (particularly water or tea, a known diuretic) prior to sleep, forcing one to get up to urinate.

Sleep interruption is a natural part of the MILD technique (described below) which trains you to arise immediately after your dreams end.

Sleep Continuity

If you have trouble initially falling asleep, avoid drinking water for about an hour before going to bed. Otherwise, you may find yourself running to the bathroom, disrupting any attempts at lucidity. Also, try to avoid caffeine and sugar before bed. However, depending on your sensitivity, caffeine may only stimulate your mind as opposed to your body. This extra grip on consciousness could be helpful in inducing lucid dreams. Exercising during the day is an excellent way of preparing your body for sleep. However, be sure to not exercise inside the three hours before bedtime, as your body will be stimulated for a short time afterwards. The morning or afternoon is the best time for this.

If you still have difficulty getting to sleep, try reading about lucid dreaming just before going to sleep. Your subconscious will likely absorb this information, increasing your chances of experiencing a lucid dream. If you *do* decide to read before going to sleep, keep a lamp next to your bed as physically getting up to turn off the lights may reawaken your body.

Reality checks

A reality check is a test you can perform to see if you're dreaming or awake. It might seem odd to test reality when you are sure that you're awake, but making a habit out of one or more of these reality checks will hugely increase your chances of having a lucid dream. If, say, you hold your nose and try to breathe in through it several times throughout the day then you're very likely to dream about doing it. And when you dream about performing a reality check, then of course the results should come out differently, in this case you'll find that you are somehow breathing in through your closed nostrils. You'll know that you're dreaming, and be able to take lucid control!

So here are some reality checks. You should be familiar with the entire list even if you only use a few.

		Reliability	**Speed**	**Discreetness**	**Overall**	**False positives**	**False negatives**
Breathing	Can you breathe with your fingers tightly sealing your nose and your mouth shut?	**5**	**5**	3	4.33	-	Very Rare
Jumping	When you jump, do you float back down?	**5**	**5**	1	3.67	-	Rare
Reading	Do sentences change when you read them? Read, turn away and repeat it to yourself, and then turn back and read it again. Do this twice.	**5**	4	4	4.33	-	Rare
Vision	Do you have perfect vision? This only works for people who have at least slightly blurry vision in the waking world. Alternatively, if you have *perfect* vision in the waking world, you may have blurred vision in the dream world.	4	**5**	**5**	4.67	-	Common
Hands	Do your hands have a strange color, too many fingers (sometimes they disappear and reappear when you try to count them!) or other abnormalities? Can you push your finger through your other hand?	4	**5**	**5**	4.67	-	Occasional
Time	Does your watch or clock tell a reasonable time? Are you even able to read the time off it? Sometimes	4	**5**	4	4.33	-	Occasional

	clocks have the wrong number of hands or have strange symbols. Try reading the time twice, like the Reading check above. Note: Digital clocks often work better for this reality check.						
Powers	Are you able to fly (just visualize it), unlock doors, or use other magical powers? Try to change the shape of your body, or walk through a wall, window, or mirror.	4	**5**	3	4	-	Common
Light switches	Does a light switch work?	4	3	1	2.67	Occasional	Occasional
Mirrors	Do you look normal in a mirror?	3	3	3	3	-	Occasional
Nose	Can you see your nose with one eye closed?	2	**5**	**5**	4	-	Rare
Memory	Are you able to remember how you got here, why you are here and what happened an hour ago?	2	3	**5**	3.33	Rare	Common
Identity	Do you have the same gender, age, job, relationships and responsibilities as usual?	2	3	**5**	3.33	-	Occasional

Choose a few reality checks which you will do regularly. Take them seriously, do not assume you are awake (even when you know you are). If you practice performing these checks very thoroughly while awake, then you're more likely to perform them thoroughly while dreaming. You should **always** carry out more than one reality check. If you find that it is not a dream, look around you and think of what would be different if it were a dream. If you do this it will make it more likely that you will do a reality check in a dream.

Apart from doing reality checks throughout the day, you also need to do a reality check immediately after you wake up. This helps you become lucid in false awakenings, when you dream that you have woken up but in fact are still dozing. Using a digital alarm clock or mobile phone display to do a Reading check, every single time you wake up, is a quick and reliable way to catch false awakenings.

If you have trouble bringing reality checks into your dreams then before going to bed imagine yourself in a dream, noticing odd details and doing a reality check. Then do a reality check in real life. If you do this a few times before bed you will find that you will do it more often in dreams.

If you are in a situation where you cannot do a reality check, such as at a public speaking, try to do one as soon as possible. You can do some reality checks very discreetly, such as looking at some text on a sign. If you start to say “well, I can't do a reality check now” you should not be surprised when you make this mistake in a dream!

Which reality checks are best?

When selecting reality checks, the most important properties of a reality check are *reliability*, *speed*, and *discreetness*.

- The **reliability** of each reality check is how likely you are to recognize the dream-sign's results as showing that you are dreaming **once you do them in a dream**. It changes for each person but some reality checks are overall more accurate than others. The figures in the table above are *rough only* and differ for each person.
- It is important for a reality check to be **fast**. It wastes dream time if you have to search around for a book or (perhaps worse) a mirror. Plus, it could also give your subconsciousness more time to produce real-life results, especially if you believe that the check will give real-life results.
- Third, a reality check should be **discreet**; that is, it should not draw too much attention to you when you do it in the waking world. Suddenly jumping in the air or trying to walk through a wall as a reality check could cause much embarrassment!
- Fourth, a reality check should not have "false positives". These occur when the reality check shows you are dreaming in real life. When you get a dream result, do another reality check to be sure!
- A final important note is whether or not a reality check should have "false negatives". These occur when a reality check shows you are in real life when you are actually dreaming. If you think you may be dreaming, keep doing tests until you prove yourself right!

On the table above, these are scored **out of 5**.

I have trouble remembering to do reality checks throughout the day. What reminders can I use?

You are lucky to have an interesting day and forget about lucid dreaming! You can tag your mind to remember dreaming when you think of certain things, like your friend or your homework. It isn't advisable to explicitly write “reality check” or “lucid” on your hand, as this could create an over dependence on this reminder, which may not exist in a dream. However, you might want to just draw a dot or small circle on your hand. This should be enough to remind you to do a reality check.

Try putting a little label on your clock, mobile phone, or watch, reminding yourself to do a reality check. (Some weird colors will make it more noticeable and it will take longer for you to get used to it and ignore it.) If you check these regularly during the course of your waking day, you will be doing lots of reality checks.

A simple coffee mug with a reminder such as "Are you dreaming?" printed on it or random alarms can also serve well, but try not to become too dependent on them. You can find examples of these at Byte Red.com and LD4All.com

Another technique is to write down three things you do regularly in a day. Examples include hearing your name, going through a doorway, turning on a TV, beginning to read a book, or seeing a stranger. In the morning, choose three such events and intend to do a reality check whenever they happen in the following day.

I did a reality check in a dream but it said that I was not dreaming. What went wrong?

Some reality checks work perfectly for some people and awfully for others. These are mostly the light switches one and the hands one. If you find that the light switch works or that your hands are perfectly normal, you need to change to a different technique.

I did a reality check in a dream but I did not quite realize I was dreaming. What went wrong?

An example of this is looking into a mirror and seeing some huge boils or a gray mist on your reflection and not realizing that you are dreaming. This is rare if you actually intended to look into the mirror as a reality check. You need to be more careful when doing your reality checks in real life or pick more reliable reality checks which show more obviously that you are dreaming. Also try to pick reality checks that are easy to do. For example, don't rely the Time Reality Check if you never wear a watch, and don't pick the Mirror Reality Check if you rarely look in the mirror during the day or you know that you won't find a mirror in your dream.

Another good remedy for this problem (and a good practice in general) is to perform two or three reality checks at a time. The Time Reality Check, for example, can be easily combined with attempting to push one hand through another. Or, for those with glasses, testing your ability to read text fits naturally with checking for "perfect eyesight w/o glasses".

Techniques

When you read through these techniques, remember that different techniques work for different people. There is no “best technique” and most techniques could be used to have 2–5 lucid dreams every night! You could have several lucid dreams in a night, but you will not know it unless you remember them!

However, you will probably want some advice as to which technique you should try first. Consider whether you want to use a method which starts from a dream or a method which starts from being awake.* If you master a technique which starts from being awake, you will eventually be able to have lucid dreams on demand when you sleep. For other techniques, you have to rely on your luck to give you lucid dreams after you have done your technique. Here are some advantages and disadvantages for specific techniques:

(Remember, it is *essential* to be able to recall at least one dream per night before attempting these techniques)

Technique	Summary	Advantages	Disadvantages	Best for...	Rating
WBTB (Wake-Back-To-Bed)	Wake after some sleep and then return to bed.	• Simple • Can be very reliable, especially when used with other techniques	• Disrupts sleep cycle	People who want to strengthen other techniques, or who wake up in the middle of the night anyway.	Green
Auto-suggestion	Let yourself genuinely believe that you'll become lucid—without *intending* to become lucid—so that you really will.	• Simple	• Less effective than some other techniques (such as MILD)	People who are susceptible to hypnosis or practice meditation.	Green
MILD (Mnemonic Induction of Lucid Dreams)	Fall asleep while focused on your intention to *remember* that you are dreaming.	• Simple	• Can be boring	People with a good prospective memory (remembrance of future intentions).	Green

WILD (Wake-Initiation of Lucid Dreams)	Keep your consciousness while falling asleep and go straight into a dream.	- Lets you truly induce lucid dreams at will	- Can cause frightening experiences - Can take long to master	People who want to reliably have lucid dreams.	Green
VILD (Visual Induction of Lucid Dreams)	By repetitive visualisation, incubate a dream in which you do a reality check.	- Also lets you induce lucid dreams at will - Works *extremely* well for some people...	- ...but not very well for others - Visualizing can keep you awake	People who have good visualization skills.	Green/ yellow
CAT (Cycle Adjustment Technique)	Adjust your sleep cycle to encourage awareness during the latter part of your sleep.	- Requires relatively little effort other than adjusting your sleep cycle - Is very effective	- Requires you to wake up early on some days - You are only likely to get a lucid dream on every other day (though this could easily be more frequently than with other techniques)	People who have a very regular sleep cycle.	Green/ yellow

[*] The usual acronyms in forums for this are DILD (Dream-Initiated Lucid Dream) and WILD (Wake-Initiated Lucid Dream). All the techniques that induce WILDs are described under WILD on this page.

WBTB

WBTB stands for “Wake-Back-To-Bed”.

Wake yourself up after 4 to 6 hours of sleep, get out of bed and stay up for anywhere between a few minutes to an hour before going back to bed. It is preferable that you do something related to lucid dreaming during this time (such as reading about lucid dreaming), but it is not required. This is best combined with other techniques; many people have amazing results with a MILD/WBTB combination. The WBTB technique significantly increases your chances of a lucid dream, and using MILD (see below) in conjunction increases your success rate if you are planning to sleep an hour or more after your WBTB session. However, you might need plenty of sleep time and therefore you may only be able to use it on weekends.

If you are sleeping too deeply to become lucid, then you can modify this technique. Try returning to sleep somewhere different than where you usually sleep, e.g. on a couch, a different bed, or even on the floor. If you are unable to do this, try changing the way you sleep, e.g. try sleeping with a lighter blanket or reversing the orientation of your body while in the bed (that is, swapping head and feet). Do this in order to teach your body that these different surroundings mean you want to have a more conscious sleep rather than a deeper sleep. In the beginning, different surroundings will also make you more alert, which can heighten your level of consciousness during sleep.

I am sometimes awake for very short times, but cannot pull myself together enough to get up and out of bed. What can I do?

Put a bright piece of paper on the wall or ceiling so that you will see it when you wake up. Other stimuli could be a hot water bottle, a light turned on under your bed, or an alarm clock. A good technique is to place an alarm clock out of arm's reach so that you are compelled to physically get up from bed and turn it off. If this is still insufficient to restore consciousness, try making a note of your intentions to remain awake and place the note on your alarm clock. After you get a lucid dream with this method, you'll find it easier and easier to get out of bed because you'll have more motivation.

Auto-suggestion

This technique describes how to use auto-suggestion to have lucid dreams. It can be especially effective for people who are highly susceptible to hypnosis or understand meditation, but for most people, MILD will probably be more effective.

As you are falling asleep, suggest to yourself that you will have a lucid dream either that night or in the near future. You can use a mantra (such as “I will recognize that I'm dreaming”) if you want, but make sure you don't try too hard to get a lucid dream. Instead of putting intentional effort into the suggestion, try to genuinely expect to have a lucid dream. Let yourself think expectantly about the lucid dream you are about to have, but be patient if you don't get one right away.

You may also use auto-suggestion to improve dream recall. Just use the technique as described above, but instead of suggesting that you'll have a lucid dream, suggest that you'll remember your dreams when you wake up. You could also use a mantra with this, such as “When I wake up, I will remember what I dreamt”. Just be careful not to put too much intentional effort into the mantra — try to genuinely expect to remember your dreams instead.

MILD

MILD stands for “Mnemonic Induction of Lucid Dreams", or sometimes, “Mnemonically Induced Lucid Dream". The MILD technique was developed by Stephen LaBerge, and is described fully in his book *Exploring the World of Lucid Dreaming*.

With the MILD technique, as you are falling asleep, you concentrate on your intention to *remember* to recognize that you are dreaming. Repeat a short mantra in your head, such as “Next time I'm dreaming, I will remember I'm dreaming”. Think about what this means (i.e., that you want to remember that you are dreaming—in the same way you might go to a grocery store and suddenly remember that you need bread), and imagine that you are back in a dream you've had recently, but this time you recognize that you are dreaming. For example, if you recently dreamed of flying, imagine realizing that it is a dream because you are flying. Keep repeating and visualizing the mantra until you are sure that your intention is set in your mind or you fall asleep. If you stop repeating and visualizing the mantra, then still try to make sure the last thing in your mind before falling asleep is your intention to remember to recognize that you are dreaming.

In general, the MILD technique can be practiced when you first go to bed at night, or after you have awakened from a dream during the night. If you practice the MILD technique after you have awakened from a dream, you should first run through the dream to ensure that you remember it. Some people find it helpful to jot down a few notes about their dream in their dream journal.

Once you have committed the dream to memory, go back to sleep and follow the steps above. But this time, visualize the dream you just had. Move through the dream in your mind until you encounter a dream-sign you originally missed. Now, instead of missing the dream-sign, imagine yourself recognizing it and becoming "lucid".

Repeat this until you have fallen asleep. You *will* re-enter the dream, and you *will* recognize the dream-sign and finally, become lucid.

WILD

WILD stands for "Wake-Initiated Lucid Dream", or "Wake-Initiation of Lucid Dreams" to refer to any technique that involves falling asleep consciously. These techniques are similar to self-hypnosis. Some people believe that WILDs are not actual dreams, but are instead astral projection. Various detailed resources are available under that moniker.

For most people, they are far easier to induce in the early morning after waking up or in afternoon naps, as the sleep cycle will continue with a REM period. Once you are experienced with inducing WILDs, you can try to induce them at other times.

For WILDs to occur, it is best for your body to be completely relaxed. When you go back to bed, lie down comfortably. Now tense and relax your body, starting from your shoulders and working downwards, then back up to the face. This (or similar relaxation, meditation, or trance techniques) should make your body feel slightly heavy and relaxed.

There are many different ways to induce WILDs, but they all involve simultaneously attempting to keep the mind aware while attempting to have the body fall asleep. A few techniques are detailed below.

If you pay attention to your physical body while using these techniques, then you will likely enter sleep paralysis (which usually happens after you are already asleep) without losing conscious awareness of your body. You will get a tingling and buzzing sensation (this might be unpleasant). These sensations might be so strong that you feel that you will die (e.g., you might feel a choking sensation), but don't worry, this is perfectly safe! In fact, this process happens to you every time you sleep, you are just not conscious during it. Sometimes you can simply wait until you fall asleep straight into a lucid dream. However, if you do not fall asleep, and you become completely paralyzed (with the exception of your eyes), do not try to move. Imagine your dream hand (or spirit hand if you prefer) going up and leaving your physical hand behind. Now you should have two separate bodies, a dream one and a real one. Control your dream body only — if you control your real one, you will wake up. Now you can try to roll out of bed into your dream world (alternatively, you can get up and walk through a mirror, or sink into your bed). There is a possibility that after waking up from a dream that you initiated using this technique, you may still be paralyzed. If this phenomenon occurs, it may be accompanied by hallucinations. For example, you may wake up from a lucid dream that you started using one of the WILD techniques, and you will still be paralyzed. A dark and scary figure may approach your bed, and you are unable to move, shout, or scream. Folklores have often given a name to this phenomenon: American people call it Old Hag , Japanese people call it kanashibari, Korean people call it kawi nullida (being pressed by a pair of scissors), and in old French it was called *Cauquemare*, which was later transformed into the term *cauchemar*.

Chakra Technique

Using Chakra ("third eye") meditation is one way to achieve WILDs. Basically, one has to focus solely on his third eye and breathing to achieve a lucid dream. This is a technique over 5000 years old, taught to Parvati by Shiva.[1] He is quoted as saying:

> With intangible breath in center of forehead, as this reaches heart at the moment of sleep, have direction over dreams and over death itself.[1]

Eyelid Patterns

This has been found to be very effective in many cases. However, it may lead to strange after effects, such as up to 15 dreams in one night, but otherwise, nothing harmful. This technique is as follows: When you go to sleep, ensure the room is completely dark. Then, with eyes closed, try to focus on the little dots that should appear to be moving on your eyelids. You will find that you can change their color at will. Continue focusing on these dots; make them dance around and form patterns and change colors, and eventually you should enter a Lucid Dream. This may take a little practice, but is usually very effective for summoning Lucid Dreams at will. Works better in conjunction with WBTB and other techniques mentioned above, but is still extraordinarily effective on its own.

Hypnagogic Imagery

Stimulate your thinking patterns by constantly switching your attention. After doing this long enough, the images and sounds should begin to take a momentum on their own (this is called hypnagogic imagery), and may they get very strange and illogical. You should enter a dream at this point and quickly become lucid. Otherwise, you will eventually realize you have entered sleep paralysis consciously (see above). Because hypnagogic sleep paralysis involves full consciousness, dreaming can sometimes be frighteningly real. There is often a feeling of being flipped upside down, spun, or being tugged upon by an outside force. Hypnagogic hallucinations may also include strange auditory hallucinations, dark beings and flying. It is possible to observe waking reality while in a hypnagogic state, but this is limited to the sensations of your physical body. Most hypnagogic sleep paralysis states occur when sleeping face up. There is evidence that the tendency toward experiencing Hypnagogic sleep paralysis may be hereditary.

Counting

Another technique is to count up to 100 in your head, optionally adding (for example) an “I'm dreaming” between each number. Alternatively, you can imagine stepping down stairs and reading each floor number, from 100 to 0. Try to make this image as vivid as possible — include not only what you see, but also what you hear, feel (touch the banister), and smell. At some point this image should continue into a dream or you will begin to get sleep paralysis as described above. It is easy to lose count, especially with counting up to 100 with an 'I'm dreaming' with each number. But stay focused: you are not going to sleep; your body is, and you must concentrate fully.

Sound Technique

This method is for people, who can hear the "tinnitus". The idea is pretty much the same as the other WILD methods, which is to remain conscious while entering the dream state. In order to use this method, you must sleep in a perfectly quiet place. You need to hear the inner buzzing sound inside your ears. Lay your body down and relax as much as possible while trying to hear the sound. If you are too tired, you will fall asleep too fast and it will be difficult to remain conscious - it this case you should combine it with WBTB. By time you realize that the buzzing sound will increase in intensity. This might frighten newcomers, but be assured - nothing bad is going to happen. No, you will not be deaf when you wake up, it’s perfectly safe! *It is just an effect caused by your brain is trying to change mode, from listening to the ambient sound, to listening to the sound of dreamland, which is not real sound but just electrical charge inputed to the part of the brain to create a sensation of hearing. By that time, you will enter the hypnagogic state. All you need to do is concentrate, do not be afraid or think of anything, just be still, and in time your dream body will float, separating from your physical body, and there you go, you arrive in the dreamworld.

Note: These sounds can be heard when you concentrate, even throughout the day - when you pay attention to them, but they shouldn't be heard much aloud if you are not in silence and concentrating on it - *as author said. The formula to hear it is quite simple: come into complete silence close your eyes and listen: is there only absolute silence or is there - something else? some...? do not create some sound just concentrate - :-) The best thing on this tech is - you can do it when you want.

Facts to know about Tinnitus

Tinnitus is a condition termed for a hissing and whistling sound that one hears in his/her ears. It's a medical term for ringing in the ears. Several reasons lead to this irritating condition and the most common cause is the damage to the nerves located inside the ear. However, there are some other factors as well such as earwax buildup, exposure to loud noises, ear infections and certain medications. Remember, the first step in finding a natural care is to determine the actual cause of tinnitus. Some Facts about Tinnitus.

The foremost thing to remember is that ringing in the ears is a symptom and not a disease. It's normal to a certain extent, however, the condition could be an indicator of a more serious condition. It's often related with hearing loss that is caused by aging. It can be a major nuisance when the ringing becomes very loud. The condition cannot be cured permanently but certainly can be eased.

Some Causes of Tinnitus

As mentioned above, ringing in the ear has some related causes and the most common out of them are damage of the cochlea due to aging (known as presbycusis), infection of the ear, exposure to loud noises and eardrum rupture. Amazingly, it has also been observed that excess ear wax buildup can also lead to this condition. Also, then there's the overuse of aspirin. Though, it's a very efficient pain reliever, its ototoxic properties (resulting into the damage to the ear) can result in tinnitus and worsen the condition in those that already have this ailment.

Tinnitus can also be developed by the usage of antibiotics, particularly amino glycoside antibiotics (a powerful form of infection fighting drug) and quinine. Also, many studies have proven the relationship between tinnitus and stress. When the brain is under stress, it has a tendency to read ordinary as well as daily sounds as fearful. After this, the tinnitus develops or becomes worse. Thus, it's very important and critical to manage stress. And if that's not enough, there are other causes for tinnitus that are not that common but are quite serious: Some of them are:

- A jaw misalignment disorder known as Temporo-Mandibular Joint (TMJ) Syndrome
- Meniere's disorder which is a disorder with recurring episodes of vertigo
- Head and neck injuries (resulting in tinnitus in one ear)
- A benign tumor known as acoustic neuroma which develops on the cranial nerve that runs from the brain to the inner ear

Treating Tinnitus

Putting in some hours with a therapist can really be beneficial and in several situations it's necessary to mental success even after the condition is alleviated. It's not easy to deal with anxiety and depression and knowing how to ignore the problem appropriately rather than indulging in it can be the best solution. It's also suggested to see a psychiatrist or psychologist who are experts with the patient suffering from the condition. This can be one of the cures for tinnitus relief and getting control over your mind can build up tolerance towards this condition which can also benefit you in dealing with other problems as well.

Masking the noise in your head can also provide you with a solution when you're trying to sleep or get rid of heavy waves of noise being produced. As tinnitus can appear loud in a silent room, leaving it on radio static can let you proper sleep. Remember, alleviating your tinnitus is only the cure for ringing in the ear as the condition can only be minimized and not completely cured.

Slight Physical Discomfort

For the purpose of helping to retain your conscious awareness, slight physical discomfort is useful while performing any WILD technique. This prevents you from just drifting off to sleep. If you are lying down on your bed to do WILD and you are totally comfortable then your chances of going to sleep instead of remaining conscious are very high. The WILD technique relies on a form of deep trance induction, and many people who induce trances for other reasons rely on slight physical discomfort — for example the lotus position, or sitting in a hard-backed chair. Depending on your own preferences and your requirements of discomfort for success, you could choose from the following methods, arranged in ascending order of discomfort:

1. Stacking pillows so that you can sit up in bed — the discomfort is caused by not being in a normal sleeping position.
2. Lying down on a hard floor.
3. Lifting your forearm vertically upwards, with the rest of your arm resting on the bed.
4. Sitting in a hard chair.

Incubating Dreams

To incubate a dream about a specific topic, you should first think of a phrase that summarizes that topic (e.g., “I want to go to Atlantis.”). It may help to write the phrase down. If there is something you want to do in the dream, think of a phrase to summarize that too (e.g., “I want to watch Atlantis sink into the ocean.”). If you want to become lucid in the dream, then you should probably write something like “When I dream of [the topic], I will remember that I'm dreaming.” beneath your topic phrase. Immediately go to sleep and focus on your topic phrase. Visualize yourself dreaming about the topic and (if you want to become lucid) realizing that you are dreaming. If there is something specific you want to do in the dream, visualize yourself doing it once you become lucid (not very likely to work if you don't become lucid in the dream). Think about your phrase and topic (and intention to become lucid) as you fall asleep. Make sure that the last thing in your mind before falling asleep is your intention to (lucidly) dream about the topic you want to dream about. You might want to wake yourself up when the dream starts to fade so that you remember more of the dream; you can do this by ignoring your perception of the dream environment — the opposite of dream stabilization techniques (just make sure you do a reality check when you wake up to make sure you are really awake).

Chaining Dreams

Dream-chaining or “chaining dreams” is a method to re-enter your dream *after you've woken up*. It can work for lucid and non-lucid dreams, but you will probably want to enter your dream lucidly.

Once you wake up from a dream (if you don't think you were dreaming before you woke up, it may not work well) you should stay still and keep your eyes closed. Small movements are okay, but the less movement, sensory stimulation, and less time awake, the better. Ideally, it should feel less like you've woken up, and more like you've taken a 30 second break from dreaming. Once you are prepared to go back to sleep, close your eyes and either visualize yourself back in your dream, or use the “spinning technique” given in the next chapter to imagine yourself spinning back “into” your dream. Spinning is a little faster than visualization. Be sure to maintain the fact that you are dreaming (unless you don't want to be lucid), or you may lose your lucidity while falling asleep. Once in the dream, stimulate your senses as early as possible (see the next chapter).

VILD

VILD stands for “Visual Induction of Lucid Dreams”, or sometimes, “Visually Incubated Lucid Dream”. This technique has been perfected by Peter Harrison, known as Pedro on the forums at ld4all.com. You may wish to read the main thread about the technique. The version described here has been adapted slightly.

First, make sure you are relaxed. You can use the relaxing technique mentioned in the description of the WILD technique. You can also imagine your brain emptying out and becoming sleepier. If you have a hard time falling asleep quickly, it should help to read a book (preferably about lucid dreaming) for a while before you go to sleep, until you feel very sleepy.

Now, you need to visualize a dream which you had prepared earlier. Here is an example of a prepared dream:

> I am in a red room with one door. A friend next to me asks me to show them what a reality check is. I do my reality checks (which show that I am dreaming), tell them that I am dreaming, and head towards the door.

Make sure you know exactly what the dream would be like, such as which friend, the exact words they say, and which reality checks you do. Reality checks that require no props, such as books or clocks, are recommended. Visualize this dream slowly three times, to make sure that you know every detail. Then, start going full-on and visualize the dream over and over. You should visualize the dream as though you are looking through your own eyes, not from a third-person perspective. If you find your thoughts drifting, ignore them and continue to visualize the dream continuously. You will need patience for this — don't just give up if you think it won't work.

When you actually dream this, you will not notice the difference — until you do your reality checks! Continue with the dream as you incubated it (e.g., remember to thank your friend!) before continuing through the door.

I tried to visualize the dream until I fell asleep, but I just stayed awake. What went wrong?

If visualizing keeps you awake, the VILD technique is not the technique for you! You should use a different technique.

LILD

LILD stands for “Lucid Induction of Lucid Dreams”, or sometimes, “Lucidly Induced Lucid Dream”.

To use this technique, you need to have a lucid dream in the first place, but it can help you to get more later. The idea is to do something in your dream that will help you to become lucid the next time you are dreaming. For example, you could ask a dream character for help — ask them to meet you the next night and tell you that you are dreaming. If it works out the way it should, then the next time you are dreaming, the dream character will walk up to you and tell you that you are dreaming, and so you'll (hopefully) become lucid. There are many variations on this technique; you could set up signs in your dreamworld that remind you to do a reality check or eat lucid pills instead! This technique is not likely to be very effective, but it *can* work; it relies on the chance that you'll subconsciously induce the reminder (i.e., the dream character or sign or whatever you used) during some later dream, and become lucid because of it.

Note that LILD is best used in conjunction with dream-signs and auto-suggested non-lucid dreams. The basic idea as explained above is to have something in your dream that triggers the transition from normal dream state to lucid dreaming. To simply tell a character to tell you that you are dreaming the next time you fall asleep is usually not enough. There is no guarantee that you will dream about that character and there is no guarantee that your subconscious will believe the character enough to make you snap into lucidity (make you realize that you are in fact dreaming).

Now as this technique suggests, you must have some previous alternate means of having a lucid dream. Whatever technique you employ to get into this initial lucid dream state is not really important, but you should try to remember to use this technique (LILD) once you do get into a lucid dream state. Thinking of this before falling asleep (MILD) sometimes helps and usually takes many lucid dreams before finally remembering. Once you are in a lucid dream, make up a dream-sign. It can be anything. It can be an object. It can be food or a drink (that doesn't taste like anything). It is usually best to pick something that isn't quite right. Something that on the surface would appear normal in the real world, but that upon closer inspection is not quite right. Food or drinks are good as they can have no taste or not be refreshing in a dream. But try and pick something that you dream about a lot so that there is a better chance of you dreaming about this dream-sign later on. Now pick something else that only appears or happens in your lucid dream. It can be anything. If there is nothing in your current lucid dream, create something really strange. Something that could never be confused with the real world. Now mentally associate the dream-sign (food) with this unusual item or event that could never happen in the real world. But at the same time, this unusual item or event should equate to "lucid dreaming". When you see the unusual item, it should only make you think of when you have a lucid dream as this should be the only time you encountered it. So we have a 3 item associative link. Do all of the above while in a lucid dream.

The next time you dream about your dream-sign, your subconscious will think of the unusual item or event. The unusual item or event will make you think of lucid dreaming. The two combined impossibilities (1. dream-sign that cannot exist in the real world 2. item or event that only appears in lucid dreams) will make your unconscious try to make a decision on all this. This will make your conscious mind come to the surface and hopefully you will come to the conclusion that you are dreaming. Many times, you will not want to deal with it because you are too tired (that is why you are sleeping, no?) and fall back into a normal dream state. This is why it can take a few tries. Eventually, your subconscious will start putting clear signs in your dreams like billboards that spell out "YOU ARE DREAMING". But once it triggers, it is quite the realization that an instant before, you had no real control over your actions and now you can do whatever you want. Another note... if it failed, you will usually know why. So next time, you can choose another dream-sign or slightly different technique or something more shocking. Once you get this working once, it is relatively easy to use over and over as the hard part just described is over with. Sometimes disassociative techniques are needed if used too much.

To sum up, this technique is a way to force a reality check while in a normal dream state where your subconscious has no choice but to come to the conclusion that you are in fact dreaming. Once your mind knows that you are dreaming, there will be no other conclusion than your conscious mind taking over. And this is what lucid dreaming is all about.

CAT

1. For one week, go to bed at the same time each night and get up 90 minutes earlier than you usually do. Spend those 90 minutes doing reality checks every 2–5 minutes.
2. Thereafter, on alternate days: follow the routine from step one, and set the intention to do your reality check routine at its regular time, while getting a full night sleep. This will cause the reality check conditioning to kick in during REM prime-time.

For detailed information on the Cycle Adjustment Technique, see the appendix on CAT : /wiki/Lucid_Dreaming/Appendices/CAT

Tibetan methods

Tibetan Buddhists practice what is known as Tibetan dream yoga. Probably the most time consuming way of inducing lucid dreams, it is also, according to the practitioners, the most rewarding. The basic practice is *awareness*. Awareness should be practiced while sleeping just as well as while being awake.

Meditating on the question “who is aware?” might catapult you into a higher degree of awareness according to Buddhist beliefs. Keeping this level of awareness is another matter. The Tibetans have developed many yogic exercises and disciplines to be practiced. Maybe the most interesting difference between Tibetan dream yoga and modern western methods of lucid dream induction is the Tibetan claim of the possibility to be aware during deep sleep, not only in the REM periods of sleep. For the reader who is interested in these methods a good start is to begin to regard all experience as a dream. After all, from the countless multitude of matter and radiation reaching our senses the nervous system tunes in only to a small fraction of this chaos. For members of the phalanx that believes we, more or less, create our own reality in the above sense this practice should feel natural. In general though, it is recommended to gain instruction from a teacher in the flesh rather than from books (like this one!).

The Tibetan Methods are not "time consuming" if the goal is to go into deeper than Lucid states. From a Raja Yoga stand point, from a Daoist standpoint, and from a Tibetan Yoga standpoint the goal is not to "play" in Lucid Dreams, but to dispel the delusional nature of what we call "reality." Also, to heal and to develop super-learning. Now "super-learning" is a relative term, it depends on your culture, modernity (in terms of entrepreneurialism - in 3rd world, 2nd world, 1st world sense; "are you developing a better rickshaw or are you developing an engine that runs off of water, what is relevant?"), and on the "energy" you find most attractive: innovative, creative, joyous, blissful, love, power, wisdom, mirth. Are you Ambitious-Worldly or Ambitious-Spiritual? All these factors play into it.

These techniques are very easy to learn and are rooted in a deeper science than the WILD, VILD, LILD -- one that does not use auto-suggestion or forced recall. In conclusion, the Tibetan methods are advanced yogic techniques that only an accomplished practitioner can fully teach. If one does not have access to a Tibetan dream yogi, one should probably concentrate on techniques that are more mundane from a Western point of view.

Other techniques

Many of these are combinations of other techniques with some addition or modification.

- **Inducing dream-signs** - You can become lucid by trying to induce specific dream-signs to watch for during your dream. You can use auto-suggestion (see above) to associate a specific dream-sign with doing a reality check, or you can just get used to doing a reality check whenever you encounter the dream-sign while awake. Some dream-signs you can use:
  - **Thirst** - Avoid drinking for very long. Wake up later in the night and put salt on your tongue or eat chili to make you even thirstier. Fill a glass of fresh cold water and take it with you back to bed. Hopefully, you'll dream of getting something to drink. Don't use this technique if you have trouble falling asleep while thirsty.
  - **False Awakening** - Set your intention as you fall asleep to wake up in the middle of the night. If you are a heavy sleeper, you'll hopefully dream of waking up in the middle of the night. If you are a light sleeper, you are probably more likely to really wake up.
  - **Bladder** - Drink large amounts of water before going to sleep. You should dream of having to go to the bathroom. You may wet your bed! This technique should be used carefully, to avoid the possibility of water intoxication.
- **Conditioning** - Strictly punish or reward yourself after a dream where you failed to realize you were dreaming or when you do have a lucid dream. This could increase motivation but not necessarily cause lucid dreams in itself. Cognitive psychology, however, states that this punishment/reward system is very counterproductive, because it ties our self-esteem to the outcome of the endeavor. The opposite of this system would be to see each attempt, including those that fail, as another step towards success.
- **Muscle Exhaustion** - Lift slight weights with one's arms and legs for about fifteen minutes before one begins to fall asleep. One should not, however, lift anything that strains the muscles too much, for that stimulates the sympathetic nervous system and excites the body. The method

should cause a release of tension in the muscles and tire them out. This combined with relaxation techniques and any of the -ILD's should produce a positive result.

Other methods

Food and drink

There are various foods and drinks that you can consume which seem to have some effect on sleeping and dreaming. Note that for most of these there is no explanation or scientific study of how they work, and some may simply be placebos.

Don't go overboard with the consumption of any of these, as overdosing could have nasty effects (well, milk should be safe unless you are allergic). **Don't experiment without accumulating enough knowledge first.** The authors in no way encourage the use of legal or illegal drugs.

- The amino acid tryptophan, which can be found in warm milk amongst other sources, is a precursor for the hormone serotonin, and has been proven to help you fall asleep.
- Vitamin B6 and others of the B group are important for neuronal functions.
- Melatonin is a hormone with neuronal effects. It is produced by the pineal gland in darkness and is suppressed by blue light. Wearing blue-blocking sunglasses or avoiding bright light in general the hours before bedtime maximizes night-time melatonin secretion.
- 5-HTP or L-5-HTP is a supplement that is related to serotonin, which some claim has induced lucid dreaming on approximately half the nights it is taken.
- Caffeine is useful in WILD techniques, as it helps the mind stay focused and think vividly. Please notice that caffeine is an addictive substance and may have negative effects on your health.
- An Amino Acid Blend made up of 2000mg L-aspartic acid, 4000mg L-glutamine, and 300mg L-theanine can substantially increase your odds of having a Lucid Dream.
- Galantamine - acetylcholinesterase inhibitors extract from plants such as *Lycoris radiata* (Red Spider Lily) or from chemical synthesis. Works best when taken together with choline and/or alpha-GPC.

Some people who practice Lucid dream (LD) or Out of body experience (OBE) use Galantamine to increase their odds to achieve LD or OBE. By taking small amount of Galantamine (around 4 to 8 mg) after 5 to 6 hours of deep sleep and practice the induction technique such as meditation, MILD or WILD many people report more success with Galantamine.

There also report that taking Galantamine without proper induction technique will not lead to LD or OBE but will result in only a vivid dream instead. It should also be noted that due to a long half life Galantamine will stay in the body for a period of up to and over 48 hours, as such it is advisable to space out the use of Galantamine over a period of three days so that the body does not build a resistance to the drug ruining its effectiveness.

Some people report mixing Galantamine with other Nootropic can enhance the degree of lucidity but this is still controversial since some mixtures may work for some people, but lead to failure for others.

Plants:

- Artemisia vulgaris
- Hypericum perforatum
- Korean Ginseng
- Valeriana officinalis
- Calea zacatechichi
- Ginkgo biloba
- Nutmeg - contains myristicin a deliriant.

For an in-depth guide to using supplements for lucid dreaming, see the book *Advanced Lucid Dreaming - The Power of Supplements*.

Drugs

Dissociatives and hallucinogens can be used to create a (more or less) lucid dream-like state, though whether or not these help with lucid dreaming is debatable. **The authors do not recommend use of these substances for induction of lucid dreams, nor do they urge the breaking of any applicable laws.**

Some dissociatives and hallucinogens are:

- Amanita muscaria
- Ayahuasca
- DMT - Common in the shamanic method of drinking Ayahuasca, to the result of entering the spirit realm. The herbal brew contains the psychedelic DMT, a drug is actually synthesized in minute quantities by the metabolism. It may be produced during dreams, adding to the enhanced experience.[2]
- DXM
- Ketamine
- LSD
- Mescaline
- Morning glory seeds
- PCP
- Psilocybe mushrooms
- Salvia divinorum

Gadgets

There are various gadgets you can use to become lucid easily. They generally detect when you are in the REM state and then provide a light and/or sound signal. This signal is supposed to be adjusted so that it doesn't wake you up but does enter your dream. The signal is then recognized as showing that you are dreaming, and you become lucid.

The most well-known device is the NovaDreamer from the Lucidity Institute. However, this product is no longer produced. Be sure to check for recommendations for devices from lucid dreaming forums.

A similar device is the DreamMaker. (http://www.wellnesstools.com/dreammaker_quickinfo.htm).The DreamMaker works very similarly to the NovaDreamer but without the Dream Alarm feature, which worked to wake the dreamer in the middle of the REM state. This device comes with a mask, a circuit board with adjustable controls, the batteries needed to operate it, a short owner's manual, a lucid dreaming workbook, and the Stephen LaBerge book *Exploring the World of Lucid Dreaming*. The circuit board is supplied completely ready to use, but you have to insert the batteries and put the circuit board into the mask yourself.

An alternative is the Kvasar (http://brindefalk.solarbotics.net/kvasar/kvasar.html). The Kvasar costs about $20 in raw materials, but needs to be constructed by somebody skilled in electronics as it is not sold commercially. It can also be hard to operate.

Another do-it-yourself alternative to commercial dreaming masks is Nate True's Lucid Dream Mask (http://cre.ations.net/creation/face-mounted-lucid-dreaming-mask),which does not bother with difficult-to-calibrate sensors and just uses a timer for flashing lights, and has (ostensibly) competitive results with all of the former gadgets.

Software

There are many programs for your computer that can assist with lucid dreaming. These can give out verbal cues while you sleep, or assist in doing your reality checks:

- iLucid Dream for the iPhone. Dream journal, reality checks, induction techniques, binaural beats for deep sleep and much more! http://cre.ations.net/creation/face-mounted-lucid-dreaming-mask. https://itunes.apple.com/us/app/ilucid-dream/id668103961?ls=1&mt=8
- Lightened Dream is available for Windows as freeware. It can be used as a dream journal and a dream-sign list. One of its more notable features is that you can have it play a voice or song each time you enter a REM sleep period. http://lucidcode.com/LightenedDream/
- DreamDoze A web application for Social Dream interpretation and dreams journal management. http://www.dreamdoze.com
- Gnaural is a multi-platform programmable binaural-beat generator. Gnaural is released as free software under the GNU General Public License. (For a browser based demo, see Gnaural Java) -- http://pantheon.yale.edu/%7Ebbl2/GnauralJavaApplet_signed.html .http://gnaural.sourceforge.net/
- Brainwave Generator is available for Windows. It works by playing binaural beats into your ears, changing your brainstate. http://www.bwgen.com
- Reality Check is available for Windows. It works by appearing on your computer screen at random times to remind you to do a reality check. http://bytered.com/software-realitycheck.html
- SBaGen is available for Windows, MacOS X, and Linux. It works by playing binaural beats into your ears, changing your brainstate. http://bytered.com/software-realitycheck.html
- Neuro-Programmer is available for Windows. This is powerful software that creates binaural beats and can work in conjunction with special goggles to induce certain mental states. http://www.transparentcorp.com
- LucidWeaver is available for mobile phones and PDA that support Java (J2ME). It includes a Dream alarm with sound cue which can be adjusted to a personal REM-sleep cycle for improving dream recall and lucidity training. Randomized reality tests can be set and it can be used as regular alarm clock.http://www.lucidweaver.com/
- Lucille 2.0 is an application to assist with doing reality checks. http://mythwell.com/lucille/index.html
- You Are Dreaming . http://www.sadglad.com/yad/yad.html
- Daldom a cross platform audio lucid dream induction software. http://www.sadglad.com/daldom/readme.html
- Lucid Dreaming Assistant DOS software (no home page) http://www.dreaminglife.org/downloads/lucid_dreaming_assistant.exe
- Unexplainable Store Lucid Dreaming Brainwave Entrainment MP3. http://www.world-of-lucid-dreaming.com/lucid-dreaming-mp3.html
- Sleep Check Reminder for Android. http://www.androlib.com/android.application.com-ropez-android-sleepcheckreminder-qDwmw.aspx
- iLucid for iOS (iPod, iPhone, iPad). https://itunes.apple.com/us/app/ilucid/id591703883?mt=8
- Sleep As Android is an Android sleep tracking app. It has a feature where it can play a sound file (by default, a soft voice that says "You're dreaming..." and echoes out) when it detects that the user is in a deep sleep. https://sites.google.com/site/sleepasandroid/

There is also a list of programs available at LD4all.com, under the “How” section.

Hypnosis

- Remotehypnosis.com has a hypnosis mp3 that can help you achieve lucid dreams.

Forums

- The World of Lucid Dreaming Forum is a good place to ask questions and receive feedback on how accurately you are performing these techniques. http://www.world-of-lucid-dreaming.com/forum/

Patents

METHOD AND APPARATUS FOR ATTAINING LUCID DREAM STATE US2010130813

Inventor(s): DOZORTSEV DMITRI

The invention discloses an apparatus that facilitates attaining of lucid dreaming state.

0001] This application claims priority of U.S. Provisional Patent Application Ser. No. 61/117424 filed Nov. 24, 2008, which is incorporated herein by reference.

TECHNICAL FIELD OF INVENTION

[0002] The present invention is in the field of apparatuses for modulation of sleep pattern.

BACKGROUND OF THE INVENTION

[0003] It is also known that some people may experience so-called lucid dreams during REM where the person is aware that he or she is dreaming while the dream is in progress. During lucid dreams, it is possible to exert conscious control over the dream characters and environment and have them perform feats which would be physically impossible in the waking world. Lucid dreams can be extremely real and vivid depending on a person's level of self-awareness during the lucid dream.

[0004] The number of people who are naturally predisposed to lucid dreaming is small.

[0005] However, there are methods that allow a not predisposed individual to experience lucid dreaming.

[0006] For example, it is well known that during night sleep humans have several episodes of dreaming accompanied by rapid eye movements (REM).

[0007] The devices for assisting lucid dreaming usually detect REM phase by monitoring eye movement using detectors mounted within the mask and then use flashing light or sound to let person know that he is dreaming without waking him up completely.

[0008] It has also been known for a long time that most men and woman experience respectively penis or clitoris erections and changes in blood flow and heart rate during the REM phase.

SUMMARY OF THE INVENTION

[0009] The disclosed invention is designed to assist an individual to enter lucid dreaming filled with sexual experience, by providing sexual stimulation when REM is detected.

DETAILED DESCRIPTION OF THE INVENTION

[0010] The disclosed apparatus has two principal parts, one detecting sexual arousal during sleep and second that provides a sexually stimulating stimulus once such arousal is detected. Because sexual arousal during sleep coincides with dreaming phase, it becomes possible for a user to introduce a sexual connotation into the dream.

[0011] Furthermore, recognizing external sexual stimulus, exerted by the apparatus, user will become aware of being dreaming, thereby transforming normal dream into lucid with sexual content.

[0012] Alternatively, the monitoring unit of disclosed apparatus may detect dream state by other means, for example by monitoring REMs or heart rate or blood pressure, skin resistance etc and send the signal to the second unit that provides sexual stimulation.

[0013] In a more simplified form, the arousal is not being monitored or detected. Instead, sexual stimulation is applied at predetermined programmed intervals during sleep.

Method and apparatus for electrically generating signal for inducing lucid dreaming US8267851

Inventor:
KROLL JAMES M

BACKGROUND OF THE INVENTIONS

1. Technical Field

The present inventions relate to dream inducement and, more particularly, relate to a method and electrical apparatus for inducing lucid dreaming.

2. Description of the Related Art

A lucid dream is one in which the dreamer obtains conscious awareness while still remaining in the dream. While we are all familiar with ordinary non-lucid dreams, the notion of conscious awareness within ones dream-space is quite foreign to most. Lucid dreaming is better understood and leveraged in Eastern culture. For example, the use of lucid dreams for personal or spiritual development has been leveraged for thousands of years in Buddhist practice. In the West, most people are too busy to apply the mental training techniques required to achieve this state naturally.

Western researchers have tried to develop technological solutions in one sense or another to solve the challenge of having lucid dreams on demand. Secondary goals of such technology driven solutions have included maximizing dream vividness, recall, control or overall cognitive ability while in the dream.

The possible applications of lucid dreaming are limitless. Not surprisingly, entertainment seems to be the most common application of lucid dreaming. This might include flying like a bird, meeting up with long lost friends or even romantic fantasies. More esoteric and well known lucid dream tasks include the elimination of recurrent nightmares, practicing physical tasks and having that practice within your dream-space impact your actual wakeful performance, elimination of phobias, insights into your subconscious by engaging in conversation with dream characters and pursuing creative endeavors such as writing music or poetry under this slightly altered state of awareness.

Given the limitless number of applications for lucid dreaming, it is desired to identify a safe and predictable method for inducing lucid dreams. While lucid dream frequency is desired, it is also important to recognize that the recovery of full cognitive ability within the dream is crucial if some of the aforementioned goals are to be implemented by the dreamer.

It is known in the art that the quality of lucid dreams can vary greatly. Perhaps the single largest challenge once lucidity is obtained is the application of full cognitive ability. Lucid dreamers will often claim they were lucid, but that their cognitive ability was a fraction of what they expect when they are awake. Ramifications of this include poor ability to remember or implement goals, or an inability to remember the details of the dream once the dreamer awakens.

An early attempt at a technological solution to lucid dreaming was the concept of a lucid dream mask by LaBerge, et al in U.S. Pat. No. 5,507,716. This was essentially a facial mask worn during a lucid dream attempt. The mask has a compartment for a printed circuit board that contains a motion detector which aligns to the position of an eye. The circuit board was designed to detect rapid eye movement (REM). Upon this detection, the mask sent light or sound cues to the dreamer. These cues may manifest in the dream as light or sound anomalies. The dreamer had to train to use these cues in order to recognize that they are dreaming. The problems with these devices were several. First, most people find it difficult to sleep with a cumbersome mask strapped to their face. Second, the settings are very tricky. A little too much motion detection sensitivity and the cues can wake the dreamer before the dream is stable. Too little and the mask doesn't detect and deliver cues. Similar problems can be said of the brightness and sound settings. The worst part is that the brain becomes accustomed to this phenomenon and tends to either tune it out or wake upon light or sound stimulus. Other peculiarities can creep in such as the lucid dreamer feeling like the mask is on them during the dream leaving them unable to see. A review of various internet lucid dream sites will find few people claiming phenomenal success with such devices.

A more recent development in lucid dream induction was that provided by LaBerge in US Patent Application Publication No. 20040266659. In this application, LaBerge identified several classes of drugs that can positively impact dream lucidity and cognitive ability of the dreamer. The main focus of this development was the class of drugs known as acetylcholine esterase inhibitors. Fundamentally, these are drugs that slow the breakdown of acetylcholine in the brain. Commercial usage of drugs such as Galantamine or Huperzine-A for lucid dream induction resulted from this disclosure by LaBerge. While this class of drugs does seem to be safe and reasonably effective at lucid dream induction, they also exhibit a number of limitations. Insomnia is a common consequence of using these drugs. Not only can this leave the subject sleepy the next day, it eliminates any possibility of lucid dreaming. Since these drugs bias acetylcholine (AcH) levels, they tend to create a chemical balance that favors REM sleep over delta wave and other physically recuperative cycles of sleep. Again, this can often leave the subject run down and sleepy the next day due to a lack of recuperative sleep the prior evening. A noticeable tolerance to acetylcholine esterase inhibitors has also been exhibited and is a common problem known to those skilled in the art. A dose that used to cause a positive effect every 4th day (generally accepted as the minimal inter-use window for galantamine), can soon only realizes a positive effect once per week. Even once a week can become a challenge for users who have leveraged a drug like galantamine for a year or more. Discussion of this tolerance issue is well documented on internet based lucid dream bulletin boards. Even with the use of these AcH boosting drugs, lucid dreamers often report unsatisfactory cognitive ability and critical thinking recovery once lucid. The last and final challenge is the gastro-intestinal distress and intolerance some people realize.

Another approach to the generalized modification of brain state activity was cranial electrical stimulation (CES). Cranial electrical stimulation was researched and developed in the Soviet Union in the 1950's. At the time this application was termed "electro-sleep" because studies focused mostly on resolution of insomnia in human subjects. By the 1960's a significant amount of private and university level research was underway in the United States for both animal and human subjects. The typical applications explored during this time were reduction of pain, anxiety, depression and elimination of insomnia.

Cranial electrical stimulation differs from several other electrical or magnetic stimuli such as transcutaneous electrical nerve stimulation (TENS) or transcranial magnetic stimulation (TMS). Cranial electrical stimulation involves the delivery of a small micro current across the brain. Typically, this is delivered via electrodes clipped to the ear lobes. The currents involved are quite small, on the order of 50 [mu]A-5 mA. Research has demonstrated that the preferred waveforms for cranial electrical stimulation applications are square or rectilinear biphasic signals with zero mean voltage delivered over time. These types of biphasic signals are easily designed and implemented to have equal positive and negative portions to eliminate the possibility of elecrolysis of the blood. This positive/negative behavior of the signal better replicates the response of nerve impulses that are characterized by having one polarity upon application of pressure and a potential of equal but opposite polarity upon release of pressure. Pulse widths of 0.1 to 2.0 seconds are commonly used and the envelope of the signal typically used for traditional applications is designed to be periodic at a rate of 0.5-3.0 Hz. It is also recognized by those skilled in the art that dynamic modification of the signal is often preferred as the brain can otherwise develop a tolerance to a repetitive electrical stimulus and slowly become unresponsive to this external signal. Methods to dynamically modify the signal include but are not limited to using on/off pulses, changing the envelope frequency over time, using a low frequency envelope to modulate a higher frequency carrier wave, changing the time domain format of the periodic signal, making changes in signal magnitude, etc.

Other cited methods are different than cranial electrical stimulation. Transcutaneous electrical nerve stimulation (TENS) for example is typically applied to injured or uncomfortable muscles and/or soft tissue areas. TENS is typically delivered in the 50-200 Hz range at much higher currents. Transcranial magnetic stimulation (TMS) differs from cranial electrical stimulation in the stimulus itself. TMS is a magnetic alteration of brain response as opposed to an electrical stimulus.

While decades of research have been implemented in this area, very little has actually been quantified in terms of how cranial electrical stimulation actually works. Most data and conclusions are empirical in nature. Blind or double blind studies routinely prove that low frequency cranial electrical stimulation in the 0.5-3.0 Hz range has positive effects in the aforementioned diseases and discomforts. Certainly it is well understood via electroencephalogram (EEG) measurements of patients before and after cranial electrical stimulation treatment that cranial electrical stimulation tends to eliminate irregular or abnormal electro chemical activity especially in the alpha range of 8-12 Hz. However the precise mechanism that drives this response is poorly understood. Most research cites the generic theory that cranial electrical stimulation helps to drive neurotransmitter balance back to a normal homeostasis. Cranial electrical stimulation regiments typically follow the model of 30 minutes of treatment per day for 5-15 days. Depending on the ailment and individual, positive response is often subjectively perceived for anywhere from 1 week to 2 years.

DIETARY SUPPLEMENT AND A METHOD TO ENHANCE SLEEP AND LUCID DREAMING
US2008107754

Inventor(s): LUCIANO JEFF

A nutritional supplement for enhancing sleep and lucid dreaming in humans. It contains a combination of ingredients in proportions calculated to enhance lucid dreaming. The primary ingredients are Calea zacatechichi, L-5-Hydroxytryptophan (L-5-HTP), and Vinpocetine. In addition, the nutritional supplement may include the secondary ingredient Melatonin and the tertiary ingredients Wild Lettuce Extract, Mugwort Extract, Dimethylaminoethanol Powder (DMAE), Passionflower Extract and Green Tea Extract. Further, various Vitamins may be added such as certain B vitamins, D and C, as well as Zinc, Magnesium and Calcium. The selection and amounts of the ingredients of the nutritional supplement promotes sleep and lucid dreaming in people who have taken the nutritional supplement prior to going to sleep.

[0001] This application claims one or more inventions which were disclosed in Provisional Application No. 60/864,801, filed Nov. 8, 2006, entitled "DIETARY SUPPLEMENT TO ENHANCE LUCID DREAMING". The benefit under 35 USC [section]119(e) of the United States provisional application is hereby claimed, and the aforementioned application is hereby incorporated herein by reference.

FIELD OF THE INVENTION

[0002] The invention pertains to the field of dietary supplements. More particularly, the invention pertains to the use of a specific dietary supplement as a sleep aid and lucid dreaming enhancer in humans.

BACKGROUND OF THE INVENTION

[0003] Dreams have been recognized as sacred and spiritual experiences in many cultures around the world since the beginning of recorded history and perhaps even earlier. In the last century, the understanding of dreams has changed from one related exclusively to the spiritual to that pertaining to the physical/psychological realm. Toward the end of the twentieth century, the idea of lucid dreaming, or dreaming with deliberate intention and control, has moved from the world of shamans or spiritualists to realization that lucid dreaming can be achieved by anyone with the assistance of nutritional supplements and practice.

[0004] In order to facilitate the understanding of lucid dreaming, it is important to understand some basic elements about sleep and common, or non-lucid, dreaming. Humans have little understanding of why we sleep and dream. It is known, though, that the most vivid dreams occur during that phase of a sleep cycle called Rapid Eye Movement, or REM. It is known that healthy human adults go through about 3-6 cycles during a normal night's sleep, with each cycle being about 90-120 minutes long. REM sleep is usually the last phase of each cycle. Dreams can occur during any phase of any cycle, however, it is known that those dreams that occur during REM sleep tend to be the most vivid and visual and are usually not directly related to current events from the dreamer's experiences during the prior day.

[0005] As scientists began to learn more about the function of the human brain, it was discovered that the stimuli that produce images in dreams originate in a part of the brain not associated with thinking, desires or wishes, but a more primitive area. This lead to the neurophysiological or synthesis activation theory of dreams in which dreams result from random stimuli from the brain stem. In accordance with this theory, the cognitive parts of the brain play a minimal part in dreaming, probably limited to trying to make sense out of the random images originating from the primitive region of the brain stem.

[0006] It is surmised that dreaming is important in the development of memory. Human infants spend up to 16-18 hours a day sleeping and approximately 50% of this is in REM sleep. It has been determined that intense sessions of learning are followed by an increase in REM sleep. Dreaming also seems to play a role in emotional adjustment and in coping with traumatic experiences.

[0007] The term "Lucid Dreaming" was first used in 1913 by Fredrich van Eeden, a Dutch physician. Lucid dreaming is perhaps best defined as being aware that you are dreaming and is most likely to occur in REM sleep. Lucid dreaming can be either low level or high level. Low level lucid dreaming means that the dreamer is aware of being in a dream, but that not all the people, animals, things and scenes are constructs of his or her mind. In high level lucid dreaming, the dreamer is not only aware of being in a dream, but that all of the elements of the dream are being generated by their mind and are therefore potentially under their complete control.

[0008] According to studies done on lucid dreaming, these dreams may not only be potentially pleasurable or wish fulfilling, they can be tools for improving the quality of the dreamer's waking lives by facilitating healing, inspiring peak athletic performances, putting an end to recurrent nightmares, overcoming phobias, reducing or eliminating various anxieties and improving problem solving capabilities.

[0009] There are methods that have been developed by various researchers in the field, such as LaBerge and Rheingold. A common technique is used by the Lucidity Institute, founded by LaBerge, and is referred to as Mnemonic Induction of Lucid Dreams ("MILD"). The basics of the MILD technique involves various steps such as deliberately making yourself wake up during a dream cycle and immediately recalling the details of the dream. Over time, the dreamer is capable of recalling all of his or her dreams. The dreamer is then directed to use a "dream sign" to use as a cue to recognize that he or she is still dreaming. Becoming proficient at lucid dreaming requires a great deal of time, dedication and practice.

[0010] In order to enhance the training of a person to develop strong lucid dreaming skills, various devices have been devised. Such devices use light and/or sound to help trigger lucid dreams. Among the shamans of some primitive cultures, they would enhance their ability to have lucid dreams by using various drugs. However, as one can imagine, most of these substances are considered illegal in the U.S. Among the legal substances known to promote sleep (and possibly dreaming) are the B-vitamins, Calea zacatechichi, melatonin, mugwort and passionflower. Before using such a substance alone or in combinations, it is important to know how to use it and what side effects it might cause. There is a need, therefore, for a safe but effective nutritional supplement that helps a person go to sleep and which can enhance lucid dreaming even without extensive mental preparation or exercises.

SUMMARY OF THE INVENTION

[0011] The present invention is a nutritional supplement that acts as a sleep aid and has been found to enhance lucid dreaming in humans. It consists of a combination of ingredients in proportions calculated to provide these results. The primary ingredients are Calea zacatechichi, L-5-Hydroxytryptophan (L-5-HTP), and Vinpocetine. A secondary ingredient is Melatonin. In addition, the nutritional supplement of the invention may include Wild Lettuce Extract, Mugwort Extract, Dimethylaminoethanol Powder (DMAE), Passionflower Extract and Green Tea Extract. Further, various B-Vitamins, vitamin D, vitamin C, magnesium, calcium, as well as Zinc, may be added.

[0012] The relative amounts of these ingredients used in the nutritional supplement will be discussed in more detail in the Detailed Description of the Invention. The use of this nutritional supplement has been seen to assist a person in going to sleep as well as helping to promote lucid dreaming in people who take the supplement prior to going to sleep.

DETAILED DESCRIPTION OF THE INVENTION

[0013] The nutritional supplement of the invention is used as a sleep aid and a promoter of lucid dreaming in people who take it prior to going to sleep. To reiterate what was stated in the Background of the Invention, lucid dreaming is defined as being aware that the dreamer is dreaming. It is most likely to occur in REM sleep and can exist either at a low level or a high level. Low level lucid dreaming means that the dreamer is aware of being in a dream, but that not all the people, animals, things and scenes are constructs of his or her mind. In high level lucid dreaming, the dreamer is not only aware of being in a dream, but that all of the elements of the dream are being generated by their mind and are therefore potentially under their complete control.

[0014] The nutritional supplement of the invention is useful in promoting lucid dreaming in people who have not necessarily trained themselves to lucidly dream by performing extensive training techniques over a long period of time. It has been formulated to provide the best effect without the need to have undergone extensive mental conditioning, such as that taught by many organization and found in various publications, or subjecting oneself to some of the known mechanical devices invented by Laberge.

[0015] The primary ingredients are Calea zacatechichi powder, L-5 Hydroxytryptophan (L-5-HTP) and Vinpocetine. A secondary ingredient is Melatonin. Additional ingredients are Wild Lettuce Extract 4:1, Mugwort Extract 4:1, Dimethylaminoethanol Powder (DMAE), Passionflower Extract 10:1 and Green Tea Extract 10:1. Further, various vitamins may be added, such as B, C and D, as well as zinc, calcium and magnesium.

[0016] All of the ingredients of the nutritional supplement of the invention are known. For instance, Calea zacatechichi is a known dream herb, used by the Chontal natives of Mexico. Green Tea is a well known drink that is high in antioxidants. Mugwort has been used for medicinal purposes for centuries and is known to cause a dreamy state of consciousness. Passionflower (Passiflora incarnate) has mild sedative properties that may be used to treat insomnia and anxiety. Wild Lettuce is an ingredient in some sleep tonics and has been historically regarded as a mild sedative. L-5-Hydroxytryptophan is known to raise serotonin levels which, in turn, improves sleep quality. Dimethylaminoethanol is thought to increase the levels of acetylcholine (a neurotransmitter) in the brain. Vinpocetine (Vinca minor) is known to aid memory and improve mental functioning. Melatonin is a natural hormone that regulates sleep in mammals. The B Vitamins are known to regulate the body's energy processes and promote good health. Vitamin C is also a necessary ingredient in maintaining good health. Zinc is used by the body in hundreds of enzymes which regulate many of the body's functions. Vitamin D, Calcium and Magnesium are additional elements that are utilized by the body.

[0017] Relative weights for the amounts of the main ingredients of the nutritional supplement are as follows:

[0000]

Weight Range	Ingredient
300-600 mg	Calea zacatechichi powder
30-70 mg	Wild Lettuce Extract 4:1
30-70 mg	Mugwort Extract 4:1
10-40 mg	L-5-HTP
5-15 mg	DMAE
14-30 mg	Passionflower Extract 10:1
5-15 mg	Green Tea Extract 10:1
1.0-4.0 mg	Vinpocetine
300-600 mcg	Melatonin

[0018] Additional ingredients, by weight:

[0000]

Range	Ingredient
0.5-2.0 mg	Vitamin B-1
5-15 mg	Vitamin B-2
10-20 mg	Vitamin B-3
10-20 mg	Vitamin B-5
5-15 mg	Vitamin B-6
100-300 mcg	Vitamin B-9
50-200 mcg	Vitamin B-12
5-15 mg	Vitamin C
1-5 mg	Zinc
20-40 mg	Magnesium
50-70 mg	Calcium
1-4 mcg	Vitamin D

[0019] A preferred formula of the nutritional supplement by weight follows:

[0000]

	amount by weight
Primary Ingredients	
Calea zacatechichi powder	500 mg
L-5-HTP	20 mg
Vinpocetine	2.5 mg
Secondary Ingredient	
Melatonin	500 mcg
Tertiary Ingredients	
Wild Lettuce Extract 4:1	50 mg
Mugwort Extract 4:1	50 mg
DMAE	10 mg
Passionflower Extract 10:1	22.5 mg
Green Tea Extract 10:1	10 mg
Additional Ingredients	
Vitamin B-1	1.4 mg
Vitamin B-2	10 mg
Vitamin B-3	15 mg
Vitamin B-5	15 mg
Vitamin B-6	10 mg
Vitamin B-9	200 mcg
Vitamin B-12	100 mcg
Vitamin C	10 mg
Zinc	3 mg
Vitamin D	2 mcg
Magnesium	30 mg
Calcium	60 mg

[0020] When considering lucid dreaming, one of the key elements, especially at a high level, is that the dreamer not only realizes they are in a dream but that they have the potential to control the progress and outcome of the dream. The following examples are summaries of testimonials of people who took the nutritional supplement of the invention as a sleep aid and not only were able to lucidly dream but were able, through their heightened awareness and control, to change what had been recurrent patterns in their dreams and their lives.

EXAMPLES

Example 1

[0021] In this example, the individual kept having recurrent nightmares over a period of about 20 years. In the dream, the person would start across a bridge and be grabbed by a monster that would begin to crush him as he was being dragged under water. When he realized that he would soon drown, he would start screaming, waking not only himself but his bed partner, as well. This person started taking the nutritional supplement of the invention and, after several more dreams like this, gradually increased his awareness, or lucidity, to the point where he was able to confront the monster and eventually was able to exercise enough control over the outcome of the dream that he killed the monster. The nightmares stopped.

[0022] Apparently, the monster was a dream created manifestation of a real person that had abused him in the past. When the dreamer and the abuser faced each other in court to resolve a legal matter, he had gained the confidence to not be afraid of the abuser any more and won the case. In this instance, the nutritional supplement of the invention allowed him, through lucid dreaming, to conquer a long entrenched fear.

Example 2

[0023] The individual in this example had been similarly experiencing recurrent nightmares since he was about 10 years old. In the nightmare, this person was chased by a dark, faceless entity and would frequently awaken screaming. However, after beginning taking the nutritional supplement of the invention, he began dreaming more and more lucidly, to the point where he soon realized that he could control his reaction to the faceless entity. He soon was able to angrily confront the entity which allowed him to rid himself of this recurrent dream. He used his experience with the recurrent nightmare that he could exercise control, through lucidly dreaming, that he could adjust his normally negative reactions to anxiety producing events in his life into positive reactions, thus enabling him to function better in the world.

[0024] Accordingly, it is to be understood that the embodiments of the invention herein described are merely illustrative of the application of the principles of the invention. Reference herein to details of the illustrated embodiments is not intended to limit the scope of the claims, which themselves recite those features regarded as essential to the invention.

SUBSTANCES THAT ENHANCE RECALL AND LUCIDITY DURING DREAMING US2004266659

Inventor(s): LABERGE STEPHEN

BACKGROUND OF INVENTION

[0001] The term "lucid dreaming" was coined by Frederik van Eeden who used the word "lucid" in the sense of mental clarity. Lucidity usually begins in the midst of a dream when the dreamer realizes that the experience is not occurring in physical reality, but is a dream. Often this realization is triggered by the dreamer noticing some impossible or unlikely occurrence in the dream, such as flying or meeting the deceased. Sometimes people become lucid without noticing any particular clue in the dream; they just suddenly realize they are in a dream. A minority of lucid dreams (according to the research of LaBerge and colleagues, about 10 percent) are the result of returning to REM (dreaming) sleep directly from an awakening with unbroken reflective consciousness. The basic definition of lucid dreaming requires nothing more than becoming aware that you are dreaming. However, the quality of lucidity can vary greatly. When lucidity is at a high level, you are aware that everything experienced in the dream is occurring in your mind, that there is no real danger, and that you are asleep in bed and will awaken shortly. With low-level lucidity you may be aware to a certain extent that you are dreaming, perhaps enough to fly or alter what you are doing, but not enough to realize that the people are dream representations, or that you can suffer no physical damage, or that you are actually in bed.

[0002] In the circumstances described above, it is strongly desired in the art to develop a safe method of aiding dreamers attempts at more frequently achieving higher states of lucidity in their dreams. One class of preferred embodiments of this invention include neurotransmitter modulators such as Acetylcholine Esterase inhibitors.

[0003] A number of substances have been suggested to enhance the likelihood of lucid dreaming, from vitamins to prescription drugs. There are few good scientific studies to back such claims. Lucid dreaming is highly subject to the placebo effect; the belief that something will stimulate a lucid dream is very effective. Many prescription drugs as well as marijuana and alcohol alter the sleep cycle, usually by suppressing REM sleep. This leads to a phenomenon called "REM rebound," in which a person experiences intense, long REM periods after the drug has worn off. This can manifest as nightmares or, possibly, as lucid dreaming, since the brain is highly active. Drugs in the LSD family, including psilocybin and tryptamines actually stimulate REM sleep (in doses small enough to allow sleep), leading to longer REM periods. The potentially dangerous and illegal nature of these drugs is not conducive to their use as lucidity enhancers.

[0004] It is known in the scientific literature that Acetylcholine and its agonist as well as Acetylcholinesterase and its inhibitors/antagonist may be involved with REM and sleeping (Amatruda et al 1975; Baghdoyan et al 1984; Gillin et al 1985; Velazquez-Moctezuma et al 1991; Wauquier et al 1985). J. A. Hobson, on page 202 of his 1988 book, "The Dreaming Brain" states: "Cholinergic brainstem mechanisms cause REM sleep and dreaming". It has also been discovered that microinjection of the Acetylcholine agonist carbachol in the certain locations of the brain, such as the Pons, elicits extended periods of REM sleep, and that many of the neurons critical for REM sleep are responsive to Acetylcholine.

[0005] Neither Hobson, nor any other others, discuss the possibility of altering Cholinergic levels via Acetylcholine Esterase inhibitors as a means of enhancing dream recall and lucidity.

[0006] Historically, there are many cultures that have believed to have found naturally occurring substances that in some way alter dream consciousness. One such substance, Calea zacatechichi or "Dream Weed", is, according to Lilian Mayagoitia, et al, in a 1986 Journal of Ethnopharmacology article, "a plant used by the Chontal Indians of Mexico to obtain divinatory messages during dreaming." The neuro-active compounds of this herb are reported to cause thought to be sesquiterpene lactones, and as far as is currently known, unrelated to Acetylcholine Esterase inhibition or inhibitors.

[0007] Both ancient traditional medicines and modern popular speculation has assigned Oneirogenic, or "Dream-Inducing" properties to numerous herbs and other natural substances, including herbs like Valerian, Mugwort, Mullein, Kava Kava, Dittany of Crete, St. Johns Wort, Salvia Divinorum, Scutellaria Indica, Licorice Root, Vervain, Jasmine, Honeysuckle, Datura, Bee Pollen, Catnip, Hops, Sculicap, Mimosa, Lavender, Damiana, Withania Somnifera, Passionflower, Chamomile, Cardamom, Gotu Kola, Ginkgo Biloba, Ibogaine, Verbena, Rose, Cinnamon, Marigold, Nutmeg, Peppermint, Holly, Yarrow and Anise. Few if any of these have any scientific basis or support for these purported effects. Other supplements and/or drugs are also claimed to be linked to lucidity, including B-vitamins, Melatonin, DMAE, and the psychedelic DXM. Some of these drugs and herbs may be addictive, poisonous and/or illegal.

[0008] Lotsof, in U.S. Pat. No. 4,499,096, issued Feb. 12, 1985, teaches a "Rapid method for interrupting the narcotic addiction syndrome" via the drug Ibogaine. According to the patent, this drug induces "dream enhancement or hallucinatory effect". This claimed "oneirogenic" effect is due to the fact that it induces dream behavior with the ego perspective relatively intact. This is, as the patent mentions, more of a hallucinatory effect, not a lucid dreaming effect. Because of these hallucinatory and other side effects, however, this drug is illegal in the U.S., and is thus not a desirable means for enhancing sleep dream quality. This drug is also not considered to be related to Acetylcholine Esterase inhibitors or 'smart drugs'.

[0009] DMAE (2-dimethylaminoethanol) is a chemical that has been suggested by used to treat a number of conditions affecting the brain and central nervous system. It is thought to work by increasing production of the neurotransmitter Acetylcholine, although this has not been proven. Marketed as a memory and mood enhancer, DMAE is believed to enhance intellectual functioning. There are few good clinical studies supporting this belief. Such substances are known as "cholinergics" because of the belief that they increase Acetylcholine. They have been traditionally used to treat diseases such as Alzheimer's dementia, tardive dyskinesia, and Huntington's chorea. Because DMAE is believed to be a cholinergic, it has been suggested for these disorders, even though placebo-controlled studies have provided essentially negative results. There is continued controversy over whether DMAE actually increases Acetylcholine. Nonetheless, Sergio, W. Claims in the 1988 August edition of Medical Hypotheses, in the article: "Use of DMAE (2-dimethylaminoethanol) in the induction of lucid dreams", subjective experiences of himself and his wife experiencing enhanced lucidity through use of this supplement. It is unclear from the article to what extent his purported results derive from placebo response or any specific or cholinergic effect.

[0010] Also well known in the art is U.S. Pat. No. 5,507,716, awarded to LaBerge, et al. on Apr. 16, 1996, for Equipment and methods used to induce lucid dreams in sleeping persons. In this patent, a device was employed to assist people to achieve lucid dreams via the detecting and monitoring the eye and head movements of sleeping persons, where eye movement activity in the absence of head movement is used to indicate the presence of REM sleep. By then applying sensory stimuli to sleepers in REM sleep can cue them that they are dreaming without producing awakening. Other persons have developed equipment, such as Keith M. T. Hearne who illustrated and described his respiratory measuring device in his 1983 U.S. Pat. No. 4,420,001. His device sensed temperature changes of a person's respiration in his or her breathing passageway, or in airflows to and from his or her breathing passageway. Thermistors were used, in an electrical circuit, to sense the temperature changes of the person's respiration. When the rate of these temperature changes reached a high predetermined level, the signals created in the electrical circuit initiated an audible sound, either to help arouse a sleeping person from an unpleasant dream by awaking them or to help them enter into a lucid dream state.

[0011] None of the preceding references disclosed describe a method of enhancing lucid dreaming comprising administering to individuals the Acetylcholine Esterase inhibitor class of drugs. Use of therapeutic agents for Alzheimer"s Disease such as Donepizil (AriceptÂ(R)), Rivastigmin (ExelonÂ(R)), Galantamine (ReminylÂ(R), NivalinÂ(R)), Tacrine and Huperzine leads to low incidence of adverse events, such as insomnia and gastrointestinal symptoms, while significantly enhancing dreaming cognitive clarity, lucidity, self-reflection, recall, control, bizarreness, and visual vividness.

SUMMARY OF INVENTION

[0012] This invention relates to the field of Lucid Dreaming and the enhancement of dream recall and dream lucidity through memory enhancing drugs, including the class of substances that comprise

Acetylcholine Esterase inhibitors (AChEIs). Lucid dreaming involves dreaming while knowing that you are dreaming. AChE inhibitors (AchEI's) inhibit the normal metabolic inactivation of Acetylcholine (ACh) by inhibiting the enzyme, Acetylcholine Esterase (AChE), leading to accumulation of Ach. AchEI's are most commonly used to enhance memory, particularly in patients suffering from Alzheimer's disease. Ach is also well known to be important in REM and thus is suggested herein to enhance dreaming and lucidity.

DETAILED DESCRIPTION

[0013] While investigating the efficacy of donepizil (AriceptÂ(R)) as a means to enhance lucid dreaming and cognitive clarity during REM sleep in normal subjects, the following experiment was performed with the following results: A randomized, double blind, placebo-controlled crossover trial was performed with ten normal volunteers self-selected for high dream recall and interest in lucid dreaming (7 male, 3 female, age 22-55). Subjects collected dream content and other self-report measures on three nights, separated by a washout period of at least one week. At bedtime, they took capsules containing 0 (placebo), 5, or 10 mg of donepizil, with counter-balanced order of the three dosages. After each spontaneous awakening during the three nights, Ss evaluated dream content on a range of measures including bizarreness, complexity, and intensity, affect, cognitive clarity, lucidity, and control. They also estimated sleep quality, insomnia, and degree of any adverse effects.

[0014] RESULTS: Nine of the 10 Ss (90%) reported one or more lucid dreams on the experimental nights, with only one S reporting a lucid dream on a placebo night. Cognitive clarity, lucidity, recall, control, bizarreness, and visual vividness were all significantly elevated with donepizil compared to placebo. The effects were generally dose-related with 10 mg donepizil producing significantly higher levels of these variables than the 5 mg dose, which in turn produced significant elevations compared to placebo. Odds of lucid dreaming for the three conditions increased from 0.031 for placebo, to 0.429 for 5 mg donepizil, and 0.754 for 10 mg donepizil. The lucidity odds ratio for the 10 mg dose compared to placebo was 24.3 ($p<0.001$). Donepizil was also associated with a significantly elevated frequency of sleep paralysis and a 40% increase in estimated time awake during the night (176 vs. 126 min of a 9.0 hr night, $p<0.05$). The incidence of adverse events, notably mild insomnia and gastrointestinal symptoms, was low and primarily associated with the higher dose condition (with two subjects reporting nausea and one vomiting).

[0015] Thus, compared to placebo, both 5 and 10 mg dosages of donepizil significantly enhance self-reported cognitive clarity, self-reflection, and lucidity during dreaming. These effects may be further enhanced by combination of the acetylcholinesterase inhibitors with Acetylcholine precursors, agonists and/or lucidity inducing electronic devices.

[0016] In addition to donepizil data, we have data on ExelonÂ(R) (rivastigmin; 6-12 mg dose) and galantamine (ReminylÂ(R), NivalinÂ(R)8-16 mg) as well. Both work as well as AriceptÂ(R)), but with perhaps fewer side effects. We have also tested huperzine with promising results, but haven't yet worked out the dose correspondence with AriceptÂ(R) (but 5 mg Donepizil is more potent than 150 Apg huperzine).

[0017] In addition, we have reports of success with nicotine patches. There is also in the scientific literature studies showing triggering/intensification of REM sleep with arecoline. How much evidence do we need for these general claims: It should be noted that the REM altering, lucidity enhancing effects may be caused by a number of neurophysiological effects induced by these "smart drugs" besides Acetylcholinesterase inhibition. These include: 1. Using a cholinergic agonist (e.g., nicotine).

[0018] 2. Using muscarinic receptor agonist: Drugs that mimic the effect of ACh on muscarinic receptors: Inc: muscarinic (M1), M2 and nicotinic Agonists. (Such as arecoline or Recoline, a muscarinic receptor agonist)3. Using an antagonist of presynaptic receptors to activate the remaining

Acetylcholine neurons. (i.e. In rats, antisense oligonucleotide sequences that block Muscarinic M2 (but not M4) receptors increases extracellular Acetylcholine. This effect (Antisense nucleotide sequences are complementary to a sequence of messenger RNA. When antisense DNA or RNA is added to a cell, it binds to a specific messenger RNA molecule and inactivates it.) 4. Using allosteric modulators (such as allosterically potentiating ligands [APLs]) of Acetylcholine and nicotinic receptors (drugs that interact with the receptor through binding sites that are distinct from those for Acetylcholine and nicotinic agonists and antagonists).

[0019] Other strategies for potentiating Acetylcholine function for dream lucidity enhancement, including the use of other classes of compound working in similar ways should be apparent to those skilled in the art from a consideration of the enclosed descriptions.

Inducing and maintaining lucid dream state, uses stimulus response for testing state of consciousness, psychological conditioning and generating lucidity

DE19920376

Inventor(s): HORNUNG HEINZ

The invention relates to a method and apparatus for achieving and maintaining a lucid dream state. The process / device offers the possibility to achieve through the use of technical means the state of lucid dreaming (lucid dream). By this is meant that the dreaming of the state in which it is located, is aware that he would say that his present experience is a dream. This finding is a "normal" dreaming inaccessible. Furthermore, it offers / her the opportunity to retain or regain this status. First, the historical development of lucid dreaming is appreciated: While in the eastern culture very early discovered and applied the possibility of lucid dream experience - for Example, in the eighth century by Tibetan Buddhists, is this phenomenon in western culture until much later - the end of the 18th Century - at the moment few people attention. 1960-1970 was only about this topic in the modern scientific research input. In recent years, a relatively large number of related publications, published in academic journals and in book form. All methods for achieving lucid dreams described in this literature is based on the following principle. By frequently as possible (ideally permanent) Check the state of consciousness in the waking state (for Example, with the questions: Am I dreaming, I wake up? etc.) is a mental conditioning can be achieved on these issues, ie a special ability to buy this in the - that this finds its way into the dream experience hope - legitimate. This approach may thus lead to the desired result, namely the clear Will the dream, if the dream I have the same questions is how confident I am that day. However, experience shows that these practices are extremely laborious, requiring a lot of time, a very large degree of discipline and lead also unfortunately only rarely successful. It should be added that experience has shown that keeping the clarity of dream is often more difficult than achieving the same. The clarity is easily lost again and then you find yourself back in the normal dream state.

For the published prior art, the following is noted: From U.S. 5,507,716, U.S. 5,551,879 and FR 2,699,412 Devices and methods are known, with the help of lucid dreaming can be caused when a sleeping person. Here, the sleeping person are given through a face mask or a kind headband stimuli that should trigger a review of the state of consciousness. These devices offer the opportunity to register eye movements and thus REM sleep phases (here are more common dreams) to detect. If there is such, optical, or acoustic signals are triggered. However, these devices affect the one hand the sleeping person in their freedom of movement in no small measure, on the other hand, and this is very much a combination with the above described procedures appears (the conditioning during the waking state) and only to a limited extent, since they are not in the normal, everyday routine can be integrated. This possibility, DE 196 47 019 (same inventor / assignee as the present invention / application). It is the closest prior art. Here, a method and an apparatus is described which / to be applied during bedtime and waking the whole of a person. During the waking state the person (with the help of technical means, such, In the manner of a wristwatch with a vibration signal) to any selected time points (e.g. Example, using a random generator, so the user completely unexpected) External stimuli supplied. The using person checked at each stimulus their state of consciousness, ie there is a conditioning to that stimulus instead. If the person now mostly identical stimuli (which are below their awakening threshold, and are preferably added in the early morning hours because the longest and most frequent REM periods occur) during sleep is supplied, it will be on the learned on the day way (a conditioned reflex after learning theory) respond to this stimulus, namely by checking their state of consciousness, and they will then conclude with a good chance that they are dreaming must. At the times of the stimuli that are triggered in this process during sleep, the following should be noted: The charms can - take place in the (general) sleep state and may not necessarily fall into a REM stage - at any time.

According to recent findings of the suppression Fund dream research is the equation of "dream sleep REM sleep equal" wrong. It is dreamed in all the other stages of sleep. If the stimuli do not fall into a dream state, the user notices nothing flat, and only the stimuli that fall into a dream state, lead to the desired effect. The proportion of time spent dreaming periods of total sleep duration is so high that even with a random choice of the timing of the stimuli fall enough stimuli to dream phases. The applicability of the first-mentioned three devices is essentially limited to the bedtime of a person and is mainly based on the scientifically validated knowledge that sleeping outside stimuli register. Since, as mentioned, a conditioning to the stimuli (light flashes, sounds) that are released from the sleep mask / the headband in the guard time hardly seems possible, the question remains on which way processes the person these charms in her dream, that is, opportunity with which these stimuli lead to a lucid dream. Significantly better chance to really achieve a lucid dream state also offers the DE 196 47 019 by the applicability of this device is extended to the whole waking state. The desired response in a dream to a stimulus (ie, checking the state of consciousness) can now be learned easily in the waking state. Based on this, the present invention seeks to provide a method and apparatus that / the shortened compared to the above methods / devices, the state of consciousness verification time and relieved and / the total increases the chance lucid dream states to reach. Furthermore, the / the present method / device to hold, or recovering the clarity in lucid dreams is to enable. This requirement of maintaining the clarity and of recovering the same is taken into account by any of the devices mentioned above. The object is achieved by a method having the features of claim 1 and by an apparatus having the features of claim 23rd Advantageous embodiments are specified in the dependent claims.

In DE 196 47 019 A method and apparatus is described in which the user's response to a single stimulus outside the review of the state of consciousness, ie, is a purely mental activity (in the waking state and during sleep). It is a simple, but fundamental difference between waking and dream states is neglected here, namely, that action leads in the waking state, as opposed to actions in the dream, to changes in the real environment. This makes the / the present method / device advantage. It / she offers the user the opportunity to advance in the specified Reizgebungsverfahren (ie, for Example, when, how and how long stimuli are given) to intervene at any time and to change it temporarily. The basic function is not affected by the surgery and will resume automatically once the operation is completed, possibly with a lag. On the one hand, a stimulus (of which the date for Was as specified by the base function) during the period in which it acts on the person changed, eg As it can be stopped by means of a special key, on the other hand can be triggered randomly at any time an extra stimulus. Trying to consciously acting to intervene in the Reizgebungsverfahren will succeed in the waking state, of course, but inevitably fail in the dream state. Thus, a situation is created which allows an immediate and clear assessment of the state in which it is located (waking state or dream state). Succeed the test of the intervention (eg Example, by stopping a currently occurring stimulus), one knows one is awake. If you fail the test, you know that you must be dreaming. The sometimes lengthy Check the currently experienced situation with the doubts and uncertainties that occur often omitted, the desired state assignment is immediately possible and absolutely clear now. Become stimuli triggered while the user is already in an at least partially lucid dream state, in this case the failure of the attempts at transforming the stimuli for strengthening, recovering and maintaining the clarity will be extremely helpful. A common, custom steady release of the above mentioned extra stimulus in the waking state, the dream state also lead to more frequent attempts to initiate this stimulus. The inevitable failure of this option also allows an immediate and clear state assignment. This increases the chance again, using the / of the present method / device to achieve or maintain lucid dream states. Even with these extra stimuli is of course the possibility of change of stimuli, which further increases the chances of success / the method / apparatus. Very useful, the ability to trigger an extra stimulus, also for the following reason.

As already mentioned, the holding of clarity during a lucid dream is often more difficult than achieving the same. Is now in such a time of doubt and danger of losing the clarity, trying to trigger an extra stimulus, the clarity is either recovered immediately, or if, contrary to expectations should not occur alone the associated view, the feeling, the hands very helpful (when using the device in the form of a wristwatch), since according to the initially mentioned method for achieving lucid dream state is a very important method for maintaining the clarity without technical aids viewing and feeling of the hands.

This is equally well with the above-mentioned possibility of change (eg Example of stopping) of a single stimulus of importance. The / the inventive method / device offers a more substantial relief to preserve the clarity. It / she offers the possibility to follow up on every single stimulus automatically in certain, freely selectable intervals other stimuli. Thus, a single stimulus of such B. 5 to 10 sec Duration at a distance of, for As one or two minutes a further stimulus 5-10 sec Duration done, etc. Instead of a single stimulus is now seen as a consequence of stimuli (duration, for B. 5 to 10 min) cast. Here, (abandonment of a single stimulus) also such a sequence of stimuli to be completed (while awake) with the above-mentioned stop button.

As in the dream state, such a termination is not possible, such a sequence of stimuli, if the clarity threatens to be lost, be very helpful to keep or regain this.
Can reaching the clarity such a sequence of stimuli to be extremely helpful, if first stimuli should not have led to the desired effect, if such B. did not fall into a dream state, or the clarity was only partially achieved. Furthermore, such a sequence of stimuli - according to the way the individual stimulus - be triggered at an arbitrarily selectable time. This may, for As happened with a special key. Here, an arbitrary delay (for , 5 to 30 min) to the first stimulus of the sequence begins, can be specified. Pressing this hot key so leads with a time delay to a sequence of individual stimuli.

It is known that the falling-asleep, whether in the evening, with interruptions (especially in the early morning hours) or during an afternoon nap in a special degree to is to achieve a more or less direct transition from twilight in a lucid dream. Here, such a sequence of individual stimuli be with delayed onset a very big help to achieve the clarity and keep. According to one embodiment, each breaks again press this button, the currently running special sequence of stimuli, even during the lag phase, from, and will automatically reboot with the given initial conditions. This is very useful if you are not asleep during the selected time delay. The very significant advantage of this opportunity, a sequence of stimuli delayed the onset of a stimulus sequence, is that herewith - as opposed to random on the night distributed stimuli or stimulus sequences - a triggering stimuli to times when the chances of success very high are is selectively enabled. The device, as described in DE 196 47 019 can also be combined with other devices, and give due to physiological measurement data stimuli or stimulus consequences. These measurement data of the other devices may be, for Example, to rapid eye movement (REM), act REM sleep EEG, heart rate increase, etc.. Additional devices may be external or integrated in the device, for Example, as a heart rate monitor. Default settings for the device, such As stimulus duration, stimulus timings etc. can be preset, on the device itself, or for B. also be a connection to a PC with appropriately developed software to be entered or changed. For the purpose of / the method / apparatus following may be cited: First, it should be mentioned here that so far are not aware of any negative side effects of lucid dreaming. Experiencing a lucid dream is consistently (which incidentally mentioned very clearly is) very pleasant and dream about the experience, as well as in the subsequent memory in the waking state, as experienced "mind-expanding". This alone makes the commercial utility of this device, specifically for home users, more than clear.

Furthermore, there are many possible applications in the field of epistemological research, especially of consciousness research, as well as in use in the psychotherapeutic treatment (eg Example, nightmares). Further details of the procedure, in particular for education of the stimuli, and the device, in particular for the design of the sensor and the controller, the combination possibilities of the device with other devices 196 47 019 A1, seen from DE, which is fully incorporated by reference.
The encoder of the present devices has all the properties described in DE 196 47 019....

Method of obtaining lucid dreaming condition
DE19647019

Inventor(s): HORNUNG HEINZ DR

The method involves giving a number of stimuli to a person, which can be recognised through one of his senses. The person's response to the stimuli give proof of the conscious state of the person and conditions the person's response, as a conditioned reflex. When this person is in a state of sleep, the same stimuli are given to him to evoke the same responses as those which were obtained while he was awake. The response to the stimuli bring about a state of lucid dreaming in which the person knows that what he experiences is a dream.

DESCRIPTION DE19647019

The invention relates to a method and apparatus for achieving a lucid dream state.
The / be presented, the novel method / device for the first time offers the opportunity through the use of technical means the state of lucid dreaming (lucid dream) reach.
By this is meant that the dreaming of the state in which it is located, is aware that he would say that his present experience is a dream.
This finding is a "normal" dreaming inaccessible.

Historical development of lucid dreaming

While in the eastern culture very early discovered and applied the possibility of lucid dream experience - for Example, in the eighth century by Tibetan Buddhists (Gillespie, G. (1988) Lucid dreams in Tibetan Buddhism. In: JI Gackenbach and S. LaBerge (Eds.), Conscious Mind, Sleeping Brain: Perspectives on Lucid Dreaming. New York:. Plenary) - takes place this phenomenon in western culture until much later - the end of the 18th Century (LaBerge, S. (1985) Lucid Dreaming. New York: Ballantine Books. German edition: Wide awake in a dream. Munich: mvg-Verlag, 1991) - at the moment few people attention. Increased interest in scientists and philosophers since the end of the 19th Century determine (Hervey de Saint-Denys, MJL (1987) Les Rèves et les Moyens de les things. Paris: Amyot. Reprinting 1964: Cercle du Livre Precieux, Paris. Übers V McCreery. Engl Edition: Dreams and How to Guide Them, Translator v. N. Fry. London: Duckworth, 1982; Myers, FWH (1887) Automatic writing - III. Proceedings of the Society for Psychical Research, 4 Part II, 209-261; Delage, Y. (1919) Le Rève. Paris: Les Presses Universitaires de France, Arnold Foster, M. (1921) Studies in Dreams. London: Allen & Unwin; Brown, AE (1936) Dreams In Which the dreamer knows he is asleep. Journal of Abnormal Psychology, 31, 59-66; Moers Messmer, H. von (1938) Dreams with the simultaneous realization of the dream state (Dreams with concurrent knowledge of the dream state). Archives of Psychology, 102, 291-318). Since 1970 this topic is in the modern scientific research input (Green, CE (1968) Lucid Dreams. London: Hamish Hamilton). In recent years, a relatively large number of related publications - in scientific journals and in book form - appeared (range: Tholey, P. (1983) Techniques for inducing and manipulating lucid dreams. Perceptual and Motor Skills, 57, 79-90; Tholey, P. (1988) A model for lucidity Training as a Means of self-healing and psychological growth. In: Gackenbach and see LaBerge, LaBerge (1985); Brylowski A. (1986) H reflex in lucid dreams. Lucidity Letter, 5 (1), 116-118; Brylowski, A. (1990) Nightmares in crisis: clinical applications of lucid dreaming techniques. Psychiatric Journal of the University of Ottawa, 15, (2), 79-84; Gillespie (1988), and J. Gackenbach Bosveld J (1989) Control your Dreams. New York: Herper & Row. German edition: ruler of the realm of dreams. Brunswick. Aurum Verlag, 1991, Hearne, KMT (1990) The Dream Machine: Lucid Dreams and how to control Them. Wellingborough, Northamptonshire: The Aquarian Press, Green, CL and Charles McCreery (1994) Lucid Dreaming, London, Routledge. German edition: Navigate dreams consciously, Frankfurt, Wolfgang Krüger Verlag, 1996). Unfortunately, research has almost exclusively in the English language with lucid dreaming, but there are German translations of some books before that, for the German research and public Currently, however, still receive little attention.

State of "technology" to achieve the lucid dream state

The previously known and applied by few persons methods to achieve lucid dreams are all based on autosuggestion. The ability to dream lucid (clear, ie conscious) can be only one "work on themselves" are obtained in the waking state. The principle underlying all these methods is the following: By frequently as possible (ideally permanent) Check the current state of consciousness - the real experience - a day (for Example, with the following questions: Am I dreaming? I wake up? Where am I? How old am I? Is it the person with whom I speak at the moment in my current life, or was there it at an earlier time? Do I have to wonder about anything? Etc ...) to a mental conditioning to be made on these issues, ie a special ability to buy and this in the hope that this finds its way into the dream experience. This hope is justified, since it is known that recur both everyday and especially intensely felt experiences of the day as so-called day residue in dreams (Freud, S. (1925) The Interpretation of Dreams, after the issue of 1972. Frankfurt am Main: Fischer Taschenbuch Verlag, 1991; dressing and Riemann (1994) Diagnosis and treatment of sleep disorders. Stuttgart Jena: Gustav Fischer Verlag Lauer et al. (1987) Shortened REM latency: A Consequence of psychological strain. Psychophysiology 24, 262-271). This approach may thus lead to the desired result, namely the clear Will the dream, if the dream I have the same questions is how confident I am that day (detailed explanation and description of these procedures is given, for Example, Green (1994)).

These procedures are according to experience extremely laborious, requiring a lot of time, a very large degree of discipline and lead also, unfortunately, only very rarely successful. A good result means that one will reach a few times a month, the state of lucid dreaming . One author reported three lucid dreams in eight years constant effort (Myers (1887)). From U.S. 5,507,716 Devices and methods are known, with the help of lucid dreaming can be caused when a sleeping person.

Here, the sleeping person will be given a sleeping mask stimuli that should trigger a review of the state of consciousness. Such a mask affects the sleeping person in their freedom of movement in no small measure.

The role and application of / the inventive process / device Based on this, the object of the invention to provide a method and apparatus that facilitate the achievement of lucid dream states or allow much in the first place. The object is achieved by a method having the features of claim 1 and by an apparatus having the features of claim 14 Advantageous embodiments are specified in the dependent claims. The above-described "work itself" is very much facilitated by the / the inventive method / device.

Many people will this / allow s method / device to achieve lucid dreams in the first place. The / the new process / device based on principles of learning theory, it is a training for practicing a conditioned reflex (eg Textbook example of the psychology of Medinzinischen sink, H. et al (1977), Munich, Vienna, Baltimore: Urban and Schwarzenberg; psychology textbook by Zimbardo / Ruch (1978), Berlin, Springer Verlag).

In the waking state are the using person - given stimuli whose time points for - preferably from outside As determined by a random generator. The individual charm reminds the person from their current intense state of consciousness (I watch? Am I dreaming? Etc ...) to question, ie the using person conditioned to this stimulus, in other words, it learns in the waking state to a certain stimulus with a very specific answer to respond, namely by questioning their current state of consciousness intense. This requires only a period of a few seconds. These charms are for both day , 10 to 20 times repeated during a more or less constant repetition is necessary in the methods used so far. According to scientific learning theory can be no doubt about the success of the vorzustellenden method. It may be mentioned here because of its popularity, the experiment of Pavlov.
This has the concept of classical conditioning, ie the formation of a conditioned reflex, already in 1900 set up (animal experiments).

Many subsequent studies have confirmed the validity of this learning principle for humans (Textbook of Medical Psychology, Enke, 1977; psychology textbook, Zimbardo / Ruch, 1978). The basic idea of the method / apparatus based on the fact that the learned in the waking state conditioned reflex can also cause during a dream, as the ability to react to stimuli, obtained even in the absence waking consciousness is like the dream research proves (shrub / Meier (1992) The dreams on the track. Results of experimental dream research, Bern: Verlag Hans Huber). For these reasons, there can be no doubt about the success of the vorzustellenden method.

For the purposes of / the method / apparatus does this mean the following. During sleep preferably identical outer stimuli are as given in the waking state. The intensity of the external stimuli is determined by the using person in the waking state so that these stimuli remain under their awakening threshold, but are nevertheless perceived by her in the dream state. (Ie, checking the state of consciousness, which with very good chance now leads to the conclusion that the dreamer on the basis of diverse absurdities of dream events come to the conclusion that he must be in a dream) allows the learned in the waking state response to this stimulus so the transition to the lucid dream experience. As with any technology device, and A method (for As cycling, driving a car), the handling must therefore be learned here, with the effort to keep discipline, effort and time with the / procedures / device within narrow limits. According to the current state of knowledge of research on the learning of a conditioned reflex is the first occurrence of lucid dreams after days, or later than expected a few weeks, depending on the susceptibility of using person. In the further application of the device, the user will in many cases after a certain time can (with increasing learning effect) waive the application of the waking state.

The purpose of the apparatus

First to be on negative effects of lucid dreaming, which could possibly be feared, received here. A short-term risk factor could be seen in an impairment of the normal recovery function of sleep. Furthermore, would imagine that lucid dreaming could in the longer those for user people have a negative effect on the attitude towards daily life.

The current state of knowledge, the research provides no evidence for both fears (for detailed discussion on the subject in Green 1994). Experiencing a lucid dream is consistently experienced by lucid dreamers to be very pleasant and as for the waking experience and the dream experience as "mind-expanding". This already established the existence of a commercial utility of this / method / apparatus, since it opens up the possibility connected with very little effort, a new "dimension" of experiencing interested persons, and thus can also offer the opportunity for personal development. Moreover, great opportunities in the epistemological research and consciousness research results. Likewise, several possibilities are conceivable to incorporate lucid dreaming into the psychotherapeutic treatment of patients. So good results in the treatment of nightmares have already shown that in patients with nightmares of unknown cause in patients with post-traumatic appearance (such Example, after an accident, rape, torture, etc.), and do not forget to children and young people who often suffer from nightmares, lucid dreaming could be a very promising treatment approach (detailed in Green 1994). But here it is again emphasized that the vorzustellende invention can be applied by anyone without risk, so it is an invention for personal use and not a medical device. Overall, let the many possibilities that could provide lucid dreaming, according to experts at the time not yet foresee...

Equipment and methods used to induce lucid dreams in sleeping persons
US5507716

Inventor(s): LABERGE STEPHEN P [US]; RICH ROBERT S [US]; WRIGHT DAVID K [US]; KOTTKE DANIEL G [US] + (LABERGE, STEPHEN P, ; RICH, ROBERT S, ; WRIGHT, DAVID K, ; KOTTKE, DANIEL

Equipment and methods employed to assist people to achieve lucid dreams (dreams in which one is aware that one is dreaming) function by detecting and monitoring the eye and head movements of sleeping persons for the presence of sufficient eye movement activity in the absence of head movement to indicate the presence of REM sleep and then applying sensory stimuli to sleepers in REM sleep, which if incorporated into their dreams, can cue them that they are dreaming without producing awakening. With this equipment and methods, people are able to have more lucid dreams than they otherwise would. A preferred embodiment includes a face mask that contains two infrared emitter-detector pairs, one for sensing eye movements and one for sensing body movements, a state-test button, and components that produce low intensity sensory stimuli such as light and sound. A microprocessor monitors the fluctuating voltage from the infrared pairs for the occurrence of a predetermined sequence of voltages, adjustable in software, and when the correct sequence occurs, triggers the stimuli-producing components in the mask into activity, to cue the sleeper to become lucid. The methods include many procedures and adjustable parameters for optimizing the timing of the application of the sensory cues to the sleeper. Among these procedures and parameters are those used to locate the time in the sleeper's REM periods when the cue will be most effective, and those used to apply the sensory stimuli at these optimal times.

BACKGROUND

As set forth in the book entitled Exploring the World of Lucid Dreaming, written by Stephen LaBerge and Howard Rheingold, the idea of cultivating a state of mind while awake for the purpose of carrying it into a dream state as a means of inducing lucid dreams, has been used by Tibetan Buddhists for more than a thousand years. However as recently as the late 1970's, experts were convinced that dreaming with consciousness that you were dreaming was a contradiction in terms and therefore impossible. At this recent time Stephen LaBerge began his Ph.D. studies of lucid dreams at Stanford University to establish proof that lucid dreaming was real, by obtaining evidence from the dream world that a person knew he or she was dreaming during sleep.

During his studies, he, with the assistance of other persons, has developed experimental testing equipment for helping him and other persons to obtain such evidence from the dream world. In so doing, the developed experimental testing equipment, in many embodiments, has also been designed and built to help persons who are lucid dreamers, or wish to try to become lucid dreamers, to have lucid dreams and to have them more often and to have them more effectively. These lucid dreamers are referred to as being Oneironauts.

Also other persons have developed equipment, such as Keith M. T. Hearne who illustrated and described his respiratory measuring device in his U.S. Pat. No. 4,420,001 of 1983. His device sensed temperature changes of a person's respiration in his or her breathing passageway, or in airflows to and from his or her breathing passageway. Thermistors were used, in an electrical circuit, to sense the temperature changes of the person's respiration. When the rate of these temperature changes reached a high predetermined level, the signals created in the electrical circuit initiated an audible sound, either to help arouse a sleeping person from an unpleasant dream by awaking them or to help them enter into a lucid dream state.

At this time, a number of different techniques have been used to monitor sleep, in both the quiet phase and active phase, the latter also being called the rapid eye movement phase of sleep and referred to as REM sleep. These techniques include applications of: electrodes for EEG, ECG and EMG; infra-red sensing; and respiration measurement with strain-gauges or thermistors. Among these techniques, Stephen LaBerge and those helping him sought a method to reliably sense the presence of REM sleep, so that a device could automatically signal to a sleeper that he or she is dreaming. The requirements for such a device were portability, ease of use, low cost, and above all reliability and the successful induction of lucid dreams, which are those dreams wherein one is aware that one is dreaming.

SUMMARY

Stephen LaBerge and those helping him created better methods to help persons lucidly dream, and, in so doing, he and those helping him developed various embodiments of experimental test equipment that is used to make sleeping persons aware they are in the active phase of their sleep, and they are having a dream, while they still continue to dream or become lucid, and such equipment senses eye movements. They selected sensing movements of a person's eyes, via movement of his or her eyelids, because by using eye movement sensing, especially when combined with body movement sensing, and thereafter accounting for such body movements, to thereby ascertain accurately eye movements, per se, they developed very reliable test equipment for detecting the phases of sleep, and especially the active phase of sleep, called the rapid eye movement phase, which is further conveniently referred to as being REM sleep.

Their development of their methods and the experimental test equipment centering on eye movement sensing, undertaken by sensing eyelid movements, which so indicate eye movements, extended over a considerable period of time. Now equipment is soon to be made available for many persons to use in practicing their methods. In respect to a preferred embodiment of the equipment each person, during his or her sleep, is provided with a comfortably worn face mask covering face portions, and a headband supports the face mask about the person's head. The face mask, in turn, supports components of this equipment, which sense a person's eyelid movements during sleep, and which, then at the proper time, signals the person that he or she is dreaming, and thus should be able to be lucidly dreaming. The signal, preferably a light signal, occurs without awaking the person. Also a sound signal is selectively and optionally used.

The sensing components supported on the face mask utilize a low level infrared emitter positioned on the face mask to direct infrared light to the eyelid of a sleeping person, and a low level infrared detector to receive the reflections of this infrared light from the surface of this eyelid of this sleeping person. The signalling components supported on the face mask preferably utilize small flashable lights and/or small speakers to signal the sleeping person that he or she is dreaming, and thus should be able to be lucidly dreaming, without awaking the person.

A like arrangement of a low level infrared emitter, also positioned and supported on the face mask, but over a part of a person's face, which does not necessarily move with a person's eyelids, is also used with a low level infrared detector also positioned and supported on the mask, to detect face, head, or body movements, which are independent of a person's eyelid movements. These body movements are accounted for to avoid erroneous conclusions as to the eyelid movements, per se, and thereby to accurately determine whether or not a person is dreaming, or could be lucidly dreaming.

The other components of this preferred embodiment of the equipment are arranged together as a shelf or table supported subassembly, with circuitry extending to the sensing and signalling components supported and positioned on the face mask, These other components include: analog signal conditioning group of components, in turn including alternating current coupling, a preamplifier, a low pass filter, a computer gain setting unit, and an integrating unit to receive signals from the infrared detector detecting eyelid movements; an analog-digital converter for converting the analog signals of the eyelid movements into digital signals; analog signal conditioning group of components, in turn including an alternating current coupling, a preamplifier, a low pass filter, a computer gain setting unit, and an integrating unit to receive signals from another infrared detector, detecting face, head, and/or body movements; an analog-digital converter for converting the analog signals of the face, head, and/or body movements into digital signals; a computer to receive the digital signal information from both the analog-digital converters, to receive signals via software instructions, to direct data to data storage, to direct signals to activate sensing lights, and to activate sensing speaker sounds...

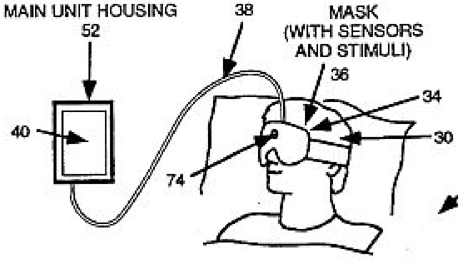

FIG. 1

LUCID DREAM STIMULATOR, SYSTEMS, AND RELATED METHODS
US2017304583

A dream stimulator may include a substrate and a plurality of electrodes positioned along a first side of the substrate. The stimulator also may include a stimulator coupled to the substrate. At least one lead may couple the plurality of electrodes to the stimulator. Additionally, a band may be positioned along a second side of the substrate and about each of the plurality of electrodes.

SYSTEMS AND METHODS FOR DELIVERING SENSORY INPUT DURING A DREAM STATE
US9620027

Embodiments of the invention provide apparatus, systems and methods for detecting neurological activity indicative of a dream state of a human. Many embodiments of the invention provide apparatus, systems and methods for detecting neurological activity of a human indicative of a dream state or the onset thereof and delivering an input to the user (such as an audio or other sensory input) during the dream state. Particular embodiments of the invention provide systems and methods for detecting neurological activity indicative of the onset or occurrence of a dream state of a human and delivering an audio or other sensory input during the user's dream state. The audio input may be used for learning, delivering messages to the user's subconscious, and/or promoting a state of relaxation.

EROTIC DREAM INDUCTION APPARATUS
US2016331924

An erotic dream induction apparatus includes an inflatable air bladder, such as a rubber balloon, to induce sexual arousal via genital stimulation. The air bladder is brought into contact with either the penis or vagina of the user, and/or is inserted into the anus and/or vagina of the user. In one embodiment, the air bladder is brought into contact with the penis, vagina, and/or anus of the user by being maintained in position near, against, or around the penis, vagina, and/or anus by means of straps or pockets in stimulation underwear, such that when the air bladder is inflated, the air bladder makes contact with at least a portion of the penis, vagina, and/or anus of the user. The air bladder is repeatedly inflated and deflated by means of pumps and/or valves.

Dream Enhancement Apparatus and Method
US2016310698

Dream stage enhancement uses a headband with EEG-EOG sensors, onboard processors, memory, coarse and fine time REM waveform detection modules, LEDs and an audio playback unit. After normalization to the user's EEG waveforms, the user's EEG-EOG signals are processed, REM and NREM stages detected and light, sound or AV stimuli are presented to the user based upon user-supplied light-sound-AV stimuli commands. To provide a reality check control ("RCC"), the head unit has a user actuatable RC interface whereby during sleep, RC stimuli are presented when the user depresses the RCC control which plays back the user supplied stimulus. In a "learning mode," the user selects "Recall" or "No Recall" ("NR") after the sleep period. If NR, then the system changes the color of light stimuli, light intensity, flash, audio sound type, audio intensity, and AV. If "Recall" the user supplied stimuli commands are carried out.

INDUCING LUCID DREAMING
WO2016209078

The present invention is in the field of induction of lucid dreams by Transcranial Alternating Current Stimulation (TACS). Lucid dreaming refers to a well-documented and scientifically accepted phenomenon that may occur during natural sleep. Lucid dreaming is characterized by awareness of the fact that one is dreaming, an increased chance of control over the events that are occurring within the dream and increased logical or rational thought during the dream.

Drug containing melatonin and phosphatidylserine
CN105708843

The invention discloses a drug containing melatonin and phosphatidylserine. The drug comprises raw materials in parts by weight as follows: 0.1-100 parts of the melatonin and 1-400 parts of phosphatidylserine. A drug preparation can be beverage, tea, tablets, granules or capsules. The drug maintains the effects of aging resistance, mental state maintenance, sleep improvement, resistance enhancement and human immune system support of the melatonin, and can treat symptoms of deficiency type dyspnea caused by long-time cough, wet dream and night emission, enuresis and frequent micturition, protracted diarrhea, spontaneous sweating, night sweat, body fluid deficiency, thirst, short breath and feeble pulse, diabetes caused by internal heat, palpitation and insomnia and the like, and due to addition of phosphatidylserine, the drug further can enhance the memory ability, prevent senile dementia, improve intelligence and the like.

Traditional Chinese medicine used for treating sexual intercourse in dream
CN104189132

The invention provides a traditional Chinese medicine used for treating sexual intercourse in dream. The traditional Chinese medicine is prepared from the following medicines: radix astragali, radix codonopsis, Chinese angelica, atractylodes macrocephala, longan, spina date seed, poria with hostwood, milkwort root, cassia twig, fossil fragments, oysters, radix glycyrrhizae preparata, Chinese dates and tuber fleeceflower stem. 700ml of water is added to first dose of the medicines to decoct the medicines until the decoction is 200ml, and 500ml of water is added to second dose of the medicines to decoct the medicines until the decoction is 200ml. The traditional Chinese medicine is taken twice a day on an empty stomach, once in the morning and once in the evening.

Non-Contact Electronic Tool for Dream Enhancement
US2013012762

This invention pertains to a non-contact electronic device for the enhancement of dreaming. By enhancement it is meant increasing the frequency, the length, the lucidity, and the color of dreaming. For example, one person who dreams in grey shades now dreams in color when using the device. The device will also allow better recall of the dreams. Dream enhancement is generally a pleasant process and promotes a pleasant feeling in the morning after use. The device is a passive electronic device, that is, it is not actively powered. The user places the device a few feet away during sleep. The device uses a piezo-crystal and an iron core. It is believed that ambient fluctuations in the piezo-crystal's voltage produce an influence field that is broadcasted through the iron core to the user a few feet away.

Method and apparatus for electrically generating signal for inducing lucid dreaming
US8267851

A lucid dream is induced in a subject. A brain state entrainment signal is generated in a circuit. A transducer applies a waveform of a kind sufficient to cause a lucid dream in the brain based on the brain state entrainment signal. The brain state entrainment signal modulates a carrier wave of a higher frequency than the entrainment frequency. The waveform is first applied to the subject and thereafter removed to attempt a lucid dream. The waveform can be electrical, light, sound or magnetic waveforms.

Dream generator
CN202198951
The utility model relates to a dream generator, comprising a luminous source and a controller for controlling the luminous source to twinkle at intervals. The luminous source is connected on a clamp. The luminous source and the controller are supplied with electricity by a power source. The utility model provides a dream generator to generate dream for people entering into sleep.

METHOD AND APPARATUS FOR ATTAINING LUCID DREAM STATE
US2010130813
The invention discloses an apparatus that facilitates attaining of lucid dreaming state. The utility model relates to a dream generator, comprising a luminous source and a controller for controlling the luminous source to twinkle at intervals. The luminous source is connected on a clamp. The luminous source and the controller are supplied with electricity by a power source. The utility model provides a dream generator to generate dream for people entering into sleep.

COMPOSITIONS, METHODS, AND SYSTEMS FOR RAPID INDUCTION AND MAINTENANCE OF CONTINUOUS REM SLEEP
WO2009100071
Compositions, kits, methods, and systems to induce, maintain, monitor, and interpret a continuous, un-fragmented REM sleep state in humans, generate dreams, recover sleep, create brain neuronal plasticity and activate the brain for cognition enhancement and mood stabilization are described. If potentially combined with other medications, a platform is provided to develop new research and therapies in many fields treating the human brain. The procedure reliably and quickly generates a Continuous REM Sleep cycle of pre-determined time or indefinite duration depending on therapeutic goals, allowing the patient to experience a qualitatively superior dream sleep in a shortened period of time compared to a natural sleep cycle. Profuse positive (pleasant) dreams are produced as well. REM sleep, dreams and sleep recovery can be reliably generated, and various sleep, psychological and neurological illnesses and disorders can be treated or prevented either solely by this method or in combination with additional agents.

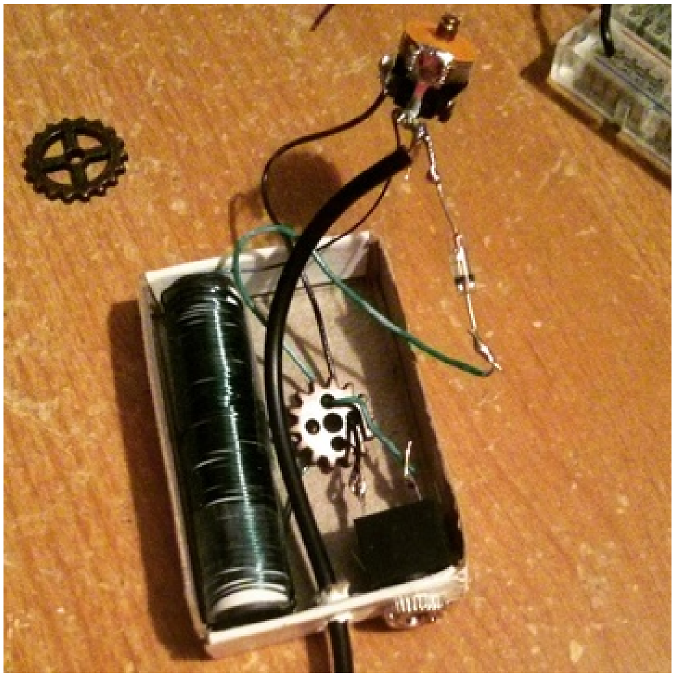
Don't buy a radio; Build one!

A Crystal Powered Steampunk Matchbox Radio

One of my friends recently had a birthday, and I got the idea to make him a simple steampunk themed matchbox radio. I'm not a steampunk expert, but I do know that devices should work without electricity. So, what better than a crystal radio?

Crystal radios in their most basic form require no electrical power, and are directly powered by the radio waves floating around us. Of course, you can add a little amplification to boost performance, like in my Altoids tin crystal radio, but it's not required.



The heart of the crystal radio is a diode used as a detector, which has the ability to pull in amplitude modulated (AM) radio signals. The most popular diode for this purpose is the 1N34 germanium diode. You should be able to find 1N34 diodes in a number of online places, or at local hamfests. I picked up a small handful at Dayton last year.

Combine the detector with a LC (inductance / capacitance) circuit and an antenna, and you have a basic *tuned radio frequency* (TRF) radio. I used the same LC circuit used in in my rocket radio circuit (a 0-100 pF variable capacitor and about 70 turns of 26 gauge magnet wire on a ferrite core).

As for the antenna, the bigger the better. Often these radios will be small and provide an alligator clip that attach to an antenna or large piece of metal. I received pretty decent reception in my area, pulling in four local AM radio stations when clipping the radio to the cold water pipes or heating duct in my house. When clipping the antenna lead to my 44' doublet, wow! You can really hear some strong signals. It's hard to believe that there's nothing powering the circuit other than radio waves.

To hear the signal (without amplification), you will need a so-called crystal earpiece, which is a special type of high impedance earphone, which are much more sensitive than regular headphones.

The schematic for a basic crystal radio looks like this:

Making a Crystal Radio - The Little Whippersnapper's Parts List

The Little Whippersnapper’s Radio requires the following widely available low-cost parts. I hope that the cost of the circuit will be within the range of the little whippersnapper’s pocket money.

Hardware

- No. 6 Brass Screws ½-inch, quantity 16 from eBay
- No. 6 Brass Cups, quantity 16 from eBay
- Baseboard must be planed softwood ½-inch thick, 4-inch wide and 12-inch long.

Germanium Diode

- OA90, Maplin Code: QH71N

Main Parts

- 365 pF Tuning Capacitor
- Ferrite Rod 3/8 inch diameter, 3-inch or longer
- 36 s.w.g enamelled copper wire / Radio coil wire
- Connecting copper wire

Tools

- Pointed nose pliers
- Screwdriver
- Gimlet / Bradawl for the guide holes
- Wire Cutter or Stripper
- Sandpaper for cleaning terminals
- Cutter pliers
- Dad / Mum / Adult Supervision

(57) ABSTRACT

This invention relates to apparatus for the conversion of massfree energy into electrical or kinetic energy, which uses in its preferred form a transmitter and a receiver both incorporating Tesla coils, the distal ends of whose secondary windings are co-resonant and connected to plates of a chamber, preferably evacuated or filled with water, such that energy radiated by the transmitter may be picked up by the receiver, the receiver preferably further including a pulsed plasma reactor driven by the receiver coil and a split phase motor driven by the reactor. Preferably the reactor operates in pulsed abnormal gas discharge mode, and the motor is an inertially damped drag motor. The invention also extends to apparatus in which an otherwise driven plasma reactor operating in pulsed abnormal gas discharge mode in turn used to drive an inertially damped drag motor.

FIG. 19

ENERGY CONVERSION SYSTEMS

This is a continuation of application Ser. No. 09/907,823, filed Jul. 19, 2001 now abandoned.

FIELD OF THE INVENTION

This invention relates to systems for the conversion of energy, inter alia in the form of what we will refer to for convenience as Tesla waves (see below), to conventional electrical energy.

BACKGROUND OF THE INVENTION

Energy converters that are fed by local or environmental energy are usually explained by taking recourse to the notion that they convert zero point electromagnetic radiation (ZPE) to electric energy. The ZPE theories have gained a life of their own, as T. Kuhn has pointed out (in his “Black Body Theory and the Quantum”), after emerging from Planck’s second theory, specifically from the term ½ hυ in the new formula for oscillator energy. In 1913, Einstein and Stern suggested that motional frequencies contributing to specific heat fell into two categories—those that were independent of temperature and those that were not (e.g. rotational energy), leading them to conclude that zero-point energy on the order of ½ hυ was most likely. In the second part of their paper, however, they provided a derivation of Planck’s Law without taking recourse to discontinuity, by assuming that the value of the ZPE was simply hυ. It is worth noting that Einstein had already in 1905 (“Erzeugung und Verwandlung des Lichtes betreffenden heuristichen Gesichtspunkt”, Ann. d. Phys, 17, 132) framed the problem of discontinuity, even if only heuristically, as one of placing limits upon the infinite energy of the vacuum state raised by the Rayleigh-Jeans dispersion law. According to Einstein, the Rayleigh-Jeans law would result in an impossibility, the existence of infinite energy in the radiation field, and this was precisely incompatible with Planck’s discovery—which suggested instead that at high frequencies the entropy of waves was replaced by the entropy of particles. Einstein, therefore, could only hope for a stochastic validation of Maxwell’s equations at high frequencies “by supposing that electromagnetic theory yields correct time-average values of field quantities”, and went on to assert that the vibration-energy of high frequency resonators is exclusively discontinuous (integral multiples of hυ).

Since then, ZPE theories have gone on a course independent from Planck’s second theory. The more recent root of modern ZPE theories stems from the work of H. Casimir who, in 1948, apparently showed the existence of a force acting between two uncharged parallel plates. Fundamentally the Casimir effect is predicated upon the existence of a background field of energy permeating even the ‘vacuum’, which exerts a radiation pressure, homogeneously and from all directions in space, on every body bathed in it. Given two bodies or particles in proximity, they shield one another from this background radiation spectrum along the axis (i.e. the shortest distance) of their coupling, such that the radiation pressure on the facing surfaces of the two objects would be less than the radiation pressure experienced by all other surfaces and coming from all other directions in space. Under these conditions, the two objects are effectively pushed towards one another as if by an attractive force. As the distance separating the two objects diminishes, the force pushing them together increases until they collapse one onto the other. In this sense, the Casimir effect would be the macroscopic analogy of the microscopic van der Waals forces of attraction responsible for such dipole-dipole interactions as hydrogen bonding. However, it is worth noting that the van der Waals force is said to tend to establish its normal radius, or the optimal distance between dipoles, as the distance where the greatest attractive force is exerted, beyond which the van der Waals forces of nuclear and electronic repulsion overtake the attraction force.

Subsequently, another Dutch physicist, M. Sparnaay, demonstrated that the Casimir force did not arise from thermal radiation and, in 1958, went on to attribute this force to the differential of radiation pressure between the ZPE radiation from the vacuum state surrounding the plates and the ZPE radiation present in the space between them. Sparnaay’s proposal is that a classical, nonquantal, isotropic and ubiquitous electromagnetic zero-point energy exists in the vacuum, and even at a temperature of absolute zero. It is further assumed that since the ZPE radiation is invariant with respect to the Lorentz transformations, it obeys the rule that the intensity of its radiation is proportional to the cube of the frequency, resulting in an infinite energy density for its radiation spectrum.

What appeared to be the virtue of this reformulated theory was the notion that the vacuum no longer figured as pure space empty of energy, but rather as a space exposed to constantly fluctuating ‘fields of electromagnetic energy’.

Puthoff has utilized the isomorphism between van der Waals and Casimir forces to put forth the zero-point (ZP) energy theory of gravity, based on the interpretation that the virtual electromagnetic ZP field spectrum predicted by quantum electrodynamics (QED) is functionally equivalent to an actual vacuum state defined as a background of classical or Maxwellian electromagnetic radiation of random phases, and thus can be treated by stochastic electrodynamics (SED). Whereas in QED, the quanta are taken as virtual entities and the infinite energy of the vacuum has no physical reality, for SED, the ZPE spectrum results from the distortion of a real physical field and does not require particle creation. Gravity then, could be seen as but the macroscopic manifestation of the Casimir force.

We do not dispute the fact that even in space absent matter there is radiant energy present which is not of a thermal nature. But we claim that this energy is not electromagnetic, nor is its energy spectrum infinite. That this is so stems not just from our opinion that it is high time that Einstein’s heuristic hypothesis should be taken as literally factual—in the dual sense that all electromagnetic energy is photon energy and all photons are local productions, but above all from the fact that it is apparent, from the experiments of Wang and his colleagues (Wang, Li, Kuzmich, A & Dogariu, A. “Gain-assisted superluminal light propagation”, Nature 406; #6793; 277), that the photon stimulus can propagate at supraluminal speeds and lies therefore well outside of any scope of electromagnetic theory, be this Maxwell’s classical approach taken up by ZPE theories, or Einstein’s special relativistic phenomenology of Maxwell’s theory. The fact is that if the light stimulus can propagate at speeds greater than those of light, then what propagates is not light at all, and thus not energy configured electromagnetically. Light is solely a local production of photons in response to the propagation of a stimulus that itself is not electromagnetic.

It is critical to understand that the implication from this that—aside from local electromagnetic radiation and from thermal radiation associated with the motions of molecules (thermo-mechanical energy), there is at least another form of energy radiation which is everywhere present, even in space absent matter. Undoubtedly, it is that energy that prevents any attainment of absolute zero, for any possible local outpumping of heat is matched by an immediate local conversion of some of this energy into a minimum thermal radiation required by the manifolds of Space and Time. And undoubtedly also this radiation is ubiquitous and not subject to relativistic transformations (i.e. Lorentz invariant). What it is not, is electromagnetic radiation consisting of randomistic phases of transverse waves.

To understand this properly, one must summarize the differences from existing ZPE theories—and all these differences come down to the fact that this energy which is neither electromagnetic nor thermal per se (and is certainly not merely thermo-mechanical), has nevertheless identifiable characteristics both distributed across subtypes or variants and as well common to all of them.

Essentially the first subtype or variant consists of longitudinal massfree waves that deploy electric energy. They could well be called Tesla waves, since Tesla-type transformers can indeed be shown experimentally to radiate massfree electric energy, in the form of longitudinal magnetic and electric waves having properties not reduceable to photon energy or to 'electromagnetic waves', and having speeds of displacement that can be much greater than the limit c for all strictly electromagnetic interactions.

One may well denote the second subtype by the designation of massfree thermal radiation, since it contributes to temperature changes—and, as obviously indicated by the impossibility of reaching an absolute zero of temperature, this contribution occurs independently of the presence of matter, or mass-energy, in Space. In other words, not all thermal radiation can be reduced to vibration, rotation and translation (drift motion) of molecules, i.e. to thermomechanical energy, because the properties of pressure and volume that determine temperature and affect matter, appear indeed to a great extent to be independent from matter, a fact which itself is responsible for the observed catastrophic and unexpected phase changes of matter and has required to this day the insufficient explanation offered semi-empirically by the Van der Waals Force Law.

Finally the third subtype may be designated latent massfree energy radiation—since it deploys neither charge, nor thermal or baroscopic effects, and yet it is responsible for 'true latent heat' or for the 'intrinsic potential energy' of a molecule. It is also responsible for the kinetoregenerative phenomenon whereby an electroscope performs a variable charge-mediated work against the local gravitational field.

The common characteristic of all three subtypes of massfree energy radiation is that they share the same nonclassical fine structure, written as follows for any energy unit, where c is any speed of light wave function, and the wavelength λ and wave function W are interconnected as a function of the physical quality of the energy field under consideration:

$$E=\lambda cW$$

In the instance of longitudinal electric radiation, this takes on the directly quantizable form:

$$E=(\lambda_q c)W_\nu=p_e W_\nu=(h/\lambda_x)W_\nu=\int=q_\nu$$

where W_ν is the voltage-equivalent wave function corresponding to V, P_e constitutes the linear momentum corresponding to the conventional q or e, h is the Planck constant, λ_x the Duane-Hunt constant expressed as a wavelength, λ_q is a wavelength constant; and the sign=∫=signifies exact equality between an expression in the conventional dimensions of length, mass and time, and an expression in length and time dimensions alone.

In the instance of massfree thermal radiation (contributing to temperature changes), the transformation obeys Boltzmann's rule (k is now Boltzmann's constant and T is Kelvin-scale temperature):

$$E=\lambda_{n1}cW_{n1}=\lambda_{n1}(\lambda_V\zeta_p)(\lambda_\alpha\zeta_{n1})=\int=kT$$

and in the third instance—of latent massfree radiation, the transformation obeys the rule:

$$E=\lambda_{n1}cW_{n1}=\lambda_{n1}(\lambda_{n1}\zeta_{n1})(\lambda_{n1}f_{n1})=\lambda_{n1}{}^3\zeta_{n1}f_{n1}$$

where ζ and f are frequency functions, f being a specific gravitational frequency term, and f_{n1} being defined as equal to $(\lambda_{n1})^{-0.5}$ meter$^{0.5}$sec^{-1}. ζ_{n1} has the value of c/λ_{n1}.

If the electric variant of massfree radiation has a direct quantum equivalence, via the Duane-Hunt Law, none of the three primary aether energy variants possess either the classic form of electromagnetic energy which requires square superimposition of speed of light wave functions c, as c^2, or the quantum form of energy, requiring $E=h\upsilon$. The critical first step in the right direction may well be attributed to Dr. W. Reich, as it regards the fact that massfree energy couples two unequal wave functions, only one of which is electromagnetic and abides by the limit c. We then unravelled the threefold structure described above, and further showed that, in the case of longitudinal electric waves, the postulated equivalence ($q=\lambda_q c$) is merely phenomenological, as these waves are not restricted by the function c in their conveying of electric charge across space. It can further be demonstrated that all blackbody photons are bound by an upper frequency limit ($64*10^{14}$ Hz), above which only ionizing photons are produced, and that all blackbody photons arise precisely from the interaction of massfree electric radiation with molecules of matter (including light leptons), whereby the energy of that radiation is locally converted into photon or electromagnetic radiation. In other words, all nonionizing electromagnetic energy appears to be secondary energy that results locally from the interaction of matter with massfree electric energy. It cannot therefore consist of the primary energy that is present in the vacuum, an energy that is neither virtual nor electromagnetic, but actual and concrete in its electric, thermal and antigravitic manifestations. Lastly, gravitational energy, being either the potential or the kinetic energy responsible for the force of attraction between units of matter, is a manifestation that also requires, much as electromagnetic radiation does, coupling of massfree energy to matter or to mass-energy.

The Tesla coil is a generator of a massfree electric energy flux that it transmits both by conduction through the atmosphere and by conduction through the ground. Tesla thought it did just that, but it has been since regarded instead (because of Maxwell, Hertz and Marconi) as a transmitter of electromagnetic energy. The transmitter operates by a consumption of massbound electric power in the primary, and by induction it generates in the coupled secondary two electric fluxes, one massbound in the coil conductor, and the other massfree in the body of the solenoid. Tesla also proposed and demonstrated a receiver for the massfree energy flux in the form of a second Tesla coil resonant with the first. The receiver coil must be identical and tuned to the transmitter coil; the capacitance of the antenna plate must match that of the transmitter plate; both transmitter and receiver coils must be grounded; and the receiver coil input and output must be unipolar, as if the coil were wired in series.

The generators of massfree energy with which we are concerned provide current pulses associated with a damped wave (DW) oscillation of much higher frequency than the pulse repetition frequency. A particular problem in recovering the massfree energy content of such pulses is provided by the damped wave oscillations. Although in our U.S. Pat. No. 5,416,391 we describe arrangements incorporating split phase motors to recover such energy, their efficiency is a great deal less than what should theoretically be attainable. Other workers such as Tesla and Reich, have encountered the same problem to an even greater degree.

In XIXth century motor engineering terminology, dynamos capable of producing direct current by continuous homopolar induction were known as 'unipolar' generators. The term unipolar induction appears to have originated with W. Weber, to designate homopolar machines where the conductor moves continuously to cut the magnetic lines of one kind of magnetic pole only, and thus require sliding contacts to collect the generated current. Faraday's rotating copper disc apparatus was, in this sense, a homopolar generator when the disc was driven manually, or a homopolar motor when the current was provided to it. Where the rotating conductor continuously cuts the magnetic field of alternatingly opposite magnetic poles, the operation of a machine, whether a generator or a motor, is said to be heteropolar. Unipolar machines went on to have a life of their own in the form of low voltage and high current DC generators—from Faraday, through Plucker, Varley, Siemens, Ferraris, Hummel, to Lord Kelvin, Pancinoti, Tesla and others—almost exclusively in the form of disc dynamos, but some having Wound rotors. In Mordey's alternator, and in so-called 'inductor alternators', however, homopolar generators were employed to obtain alternating currents, with the use of rotors wound back and forth across the field. Use of smooth, unwound rotors in AC induction motors (as opposed to AC synchronous motors, such as hysteresis motors) was a later development than homopolar dynamos. By 1888, Tesla and Ferraris amongst still others, had independently produced rotating magnetic fields in a motor, by employing two separate alternate currents with the same frequency but different phase. Single phase alternate current motors were developed later, and split-phase motors were developed last. Ferraris (Ferraris, G (1888) "Rotazioni elettrodynamiche", Turin Acad, March issue.) proposed the elementary theory of the 2-phase motor, where the current induced in the rotor is proportional to the slip (the difference between the angular velocity of the magnetic field and that of the rotating cylinder), and the power of the motor is proportional to both the slip and the velocity of the rotor.

If an iron rotor is placed within the rotating magnetic field of a 2-phase stator, it will be set in rotation, but not synchronously, given that it is always attracted to the moving magnetic poles with a lag. But if an aluminum or copper rotor is used instead, it becomes 'dragged' around by the rotating stator field because of the eddy currents induced in it. If the aluminum or copper rotor were to rotate synchronously with the stator magnetic field, there would be no induced eddy currents and thus no motor action would result. The motor action depends, in this instance, upon the presence of asynchronous slip, since the function of the latter is to sustain the induction of those currents in the rotor that are responsible for the motor action of the dragged rotor. This then is the origin of the term 'AC drag motors'. Once the drag rotor evolved from a cylinder to a hollow cup, they earned the epithet of 'drag-cup motors'. Later, already in the XXth century, the cups were fitted over a central stator member, and the sleeve rotor 2 phase servomotor was born.

Tesla knew that impulse currents as well as CW sinusoidal currents could be used to drive AC motors. Regarding his invention of an hysteresis motor ('magnetic lag motor', as he called it), he stated: " . . . pulsatory as well as an alternating current might be used to drive the[se] motors . . . " (Martin, TC (1894) "The inventions, researches and writings of Nikola Tesla", Chapter XII, p. 68). In his search for efficient utilization of the high frequency DW impulse currents of his induction coils, Tesla began by employing an AC disc induction motor as shown in FIG. **17** of his famous 1892 address (Tesla, N (1892) "Experiments with alternate currents of high potential and high frequency", in "Nikola Tesla Lectures", 1956, Beograd, pp. L-70–71). This consisted of a copper or aluminum disc mounted vertically along the longitudinal axis of an iron core on which was wound a single motor coil which was series wired to the distal terminal of an induction coil at one end, and to a large suspended and insulated metal plate at the other. What was new about this was the implementation of an AC disc induction motor drive, where the exciting current traveled directly through the winding with just a unipolar connection to the coil secondary (under certain conditions, even the series connection to the plate could be removed, or replaced with a direct connection to the experimenter's body): "What I wish to show you is that this motor rotates with one single connection between it and the generator" (Tesla, N. (1892), op. cit., L-70, Tesla's emphasis). Indeed, he had just made a critical discovery that, unlike in the case of massbound charge where current flow requires depolarization of a bipolar tension, massfree charge engages current flow unipolarly as a mere matter of proper phase synchronization.

Tesla thought that his motor was particularly adequate to respond to windings that had 'high-self-induction', such as a single coil wound on an iron core. The basis of this self-induction is the magnetic reaction of a circuit, or an element of a circuit—an inductor—whereby it chokes, dims or dampens the amplitude of electric waves and retards their phase.

For the motor to respond to still higher frequencies, one needed to wind over the primary motor winding a partial overlap secondary, closed through a capacitor, since "it is not at all easy to obtain rotation with excessive frequencies, as the secondary cuts off almost completely the lines of the primary" (Idem, L-71.).

Tesla stated that "an additional feature of interest about this motor" was that one could run it with a single connection to the earth ground, although in fact one end of the motor primary coil had to remain connected to the large, suspended metal plate, placed so as to receive or be bathed by "an alternating electrostatic field", while the other end was taken to ground. Thus Tesla had an ordinary induction coil that transmitted this "alternating electrostatic field", an untuned Tesla antenna receiving this "field", and a receiver circuit comprising his iron-core wound motor primary, a closely coupled, capacitatively closed secondary, and the coupled nonferromagnetic disc rotor. Eventually, in his power transmission system, he would replace this transmitter with a Tesla coil, and place an identical receiving coil at the receiving end, to tune both systems and bring them into resonance. But his motor remained undeveloped, and so did the entire receiver system.

Tesla returned to this subject a year later: "on a former occasion I have described a simple form of motor comprising a single exciting coil, an iron core and disc" (Tesla, N (1893) "On light and other high frequency phenomena", in "Nikola Tesla Lectures", 1956, Beograd, pp. L-130, and L-131 with respect to FIG. **16**-II). He describes how he developed a variety of ways to operate such AC motors unipolarly from an induction transformer, and as well other arrangements for "operating a certain class of alternating motors founded on the action of currents of differing phase". Here, the connection to the induction transformer is altered so that the motor primary is driven from the coarse secondary of a transformer, whose finer primary is coupled, at one end, directly and with a single wire to the Tesla secondary, and at the other left unconnected. On this occasion, Tesla mentions that such a motor has been called a 'magnetic lag motor', but that this expression (which, incidentally, he had himself applied to his own invention of magnetic hysteresis motors) is objected to by "those who attribute the rotation of the disc to eddy currents when the core is finally subdivided" (Tesla,N (1893), op. cit., p. L-130).

In none of the other motor solutions, 2-phase or split-phase, that he suggests as unipolar couplings to the secondary of an induction coil, does the nonferromagnetic disc rotor motor again figure. But he returns to it a page later, and indirectly so, by first addressing the disadvantages of ferromagnetic rotors: "Very high frequencies are of course not practicable with motors on account of the necessity of employing iron cores. But one may use sudden discharges of low frequency and thus obtain certain advantages of high-frequency currents-without rendering the iron core entirely incapable of following the changes and without entailing a very great expenditure of energy in the core. I have found it quite practicable to operate, with such low frequency disruptive discharges of condensers, alternating-current motors."

In other words—whereas his experiments with constant wave (CW) alternating currents, and as well with high-voltage DW impulses from induction coils, indicated the existence of an upper frequency limit to iron core motor performance, one might employ instead high-current, DW impulses—of high DW frequencies but low impulse rates—to move these motors quite efficiently. Then he adds "A certain class of [AC] motors which I advanced a few years ago, that contain closed secondary circuits, will rotate quite vigorously when the discharges are directed through the exciting coils [emphasis added]. One reason that such a motor operates so well with these discharges is that the difference of phase between the primary and secondary currents is 90 degrees, which is generally not the case with harmonically rising and falling currents of low frequency. It might not be without interest to show an experiment with a simple motor of this kind, inasmuch as it is commonly thought that disruptive discharges are unsuitable for such purposes."

What he proposes next forms the basis of modern residential and industrial AC electric power meters, the AC copper disc motor whose rotor turns on the window of these meters, propelled forward by the supply frequency. But instead of employing any such CW input, Tesla uses the disruptive discharges of condensers, incipiently operating as current rectifiers. With the proper conditions, e.g. correct voltage from the generator, adequate current from the capacitor, optimum capacitance for the firing rate, and tuned spark-gap, to mention a few, Tesla found that the nonferromagnetic disc rotor turned but with considerable effort. But this hardly compared to the results obtained with a high-frequency CW alternator, which could drive the disc "with a much smaller effort". In summary then, Tesla went as far as being the first to devise a motor driven by Tesla waves, that employed a nonferromagnetic rotor, and whose arrangement encompassed both transmitter and receiver circuits. For this purpose, he employed a single phase method in which the signal is fed unipolarly to the winding, placed in series with a plate capacitance.

Tesla also later proposed driving a similar single-phase nonferromagnetic disc motor from bipolar capacitative discharges through an atmospheric spark-gap now placed in parallel with the main motor winding, and again simulating a split-phase by a closely wound secondary that was closed by a capacitance.

As Tesla admits, the results of all his AC eddy current motor solutions were meagre and limited by current and frequency problems. Likewise, the two phase arrangements proposed by Reich for his OR motor, involving a superimposition of the damped waves of a first phase on a fixed continuous wave second phase, require an external power source and a pulse amplifier circuit, and failed to meet Reich's own desiderata.

We have previously proposed the use of squirrel cage motors with capacitative splitting of phase to convert the damped wave (DW) output of plasma pulsers, but once a squirrel cage (SC) is introduced, the dampening effect which the nonferromagnetic copper cage exerts in being dragged by the revolving stator field is counteracted by the ferromagnetic cylinder of laminated iron, in which the copper cage is embedded, working to diminish the slip and bring the rotor to near synchronism. This is, in all likelihood, what limits SC motors to responding to the DC component of the DW impulse, and thus be limited to respond to fluxes of massbound charges. Historically, as we shall see, the obvious advantage of the SC servomotors lay in the fact that, in particular for 2-phase applications, they were far more efficient at performing work without evolution of heat. Indeed, if the eddy currents in the nonferromagnetic rotor are permitted to circulate in nonordered form, the rotor material and stator will heat up rapidly and consume much power in that heating. This is in fact considered to be a weakness of AC nonferromagnetic-rotor induction motors.

SUMMARY OF THE INVENTION

The present invention is concerned with conversion to conventional electrical energy of the variants of massfree energy radiation considered above, referred to for convenience as Tesla waves, massfree thermal radiation and latent massfree radiation. The first variant of such radiation was recognized, generated and at least partially disclosed by Tesla about a hundred years ago, although his work has been widely misinterpreted and also confused with his work on the transmission of radio or electromagnetic waves. The Tesla coil is a convenient generator of such radiation, and is used as such in many of the embodiments of our invention described below, but it should be clearly understood that our invention in its broadest sense is not restricted to the use of such a coil as a source of massfree radiation and any natural or artificial source may be utilized. For example, the sun is a natural source of such radiation, although interaction with the atmosphere means that it is largely unavailable at the earth's surface, limiting applications to locations outside of the earth's atmosphere.

According to the invention, a device for the conversion of massfree radiation (as herein defined) into electrical or mechanical energy comprises a transmitter of massfree electrical radiation having a damped wave component, a receiver of such radiation tuned to resonance with the damped wave frequency of the transmitter, a co-resonant output circuit coupled into and extracting electrical or kinetic energy from the receiver, and at least one of structure defining a transmission cavity between the transmitter and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed plasma discharge device incorporated in the co-resonant output circuit. The output circuit preferably comprises a full wave rectifier presenting a capacitance to the receiver, or an electric motor, preferably a split phase motor, presenting inductance to the receiver. The transmitter and receiver each preferably comprise a Tesla coil and/or an autogenous pulsed abnormal glow discharge device. The transmission cavity is preferably at least partially evacuated, and comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively, the plates being parallel or concentric. The structure defining the cavity may be immersed in ion-containing water. The split-phase motor is preferably an inertially damped AC drag motor.

The invention, and experiments demonstrating its basis, are described further below with reference to the accompanying drawings.

SHORT DESCRIPTION OF THE DRAWINGS

FIG. **1** is a schematic view of a Tesla coil connected to a full-wave rectifier to form an energy conversion device;

FIG. **2** is a schematic view of a Tesla coil connected to a gold leaf electrometer;

FIGS. **3**–**6** show alternative electrometer configurations;

FIGS. **7**–**11** show modifications of the circuit of FIG. **1**;

FIG. **12** shows apparatus for investigating aspects of the experimental results obtained with the foregoing devices;

FIG. **13** is a graph illustrating results obtained from the apparatus of FIG. **12**;

FIGS. **14**–**17** show schematic diagrams of embodiments of energy conversion devices;

FIG. **18** is a diagrammatic cross section of an inertially damped drag cup motor; and

FIG. **19** is a schematic diagram of a further embodiment of energy conversion device incorporating such a motor.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Based upon observations of weight loss in metallic matter as induced by exposure to high frequency alternating electric fields, we developed an experimental method to optimize this weight loss, and from this a device that treats the forces causing weight loss as manifestations of intrinsic potential energy ΔU (or true "latent heat") of the molecules of matter, and converts both "true latent heat" energy present in the neighbourhood of a receiver, and "sensible" heat induced within that receiver, into electric energy that can be employed to drive a motor, flywheel or charge battery supplies.

It is commonly believed that the output of the Tesla coil is ionizing electromagnetic radiation. We have demonstrated that it is not; i.e. that it is neither electromagnetic radiation, nor ionizing electromagnetic radiation. The output of an air cored, sequentially-wound secondary, consists exclusively of electric energy: upon contact with the coil, a massbound AC current can be extracted at the resonant frequency, whilst across a non-sparking gap, massfree AC-like electric wave radiation having the characteristics of longitudinal waves, can be intercepted anywhere in adjacent space. Accordingly, the radiation output from such coils is distinct from electromagnetic radiation.

The basic demonstration that the output of a Tesla coil does not consist of ionizing radiation is that it does not accelerate the spontaneous discharge rate of electroscopes, whether positively or negatively charged. In fact, in its immediate periphery, the coil only accelerates the spontaneous discharge rate of the negatively charged electroscope (i.e. the charge leakage rate), whereas it arrests the discharge of the positively charged electroscope (i.e. the charge seepage rate falls to zero). But this dual effect is not due to any emission of positive ions from the secondary, even if it can positively charge a discharged electroscope brought to its proximity. This charging effect is in fact an artifact, in that metals but not dielectrics are ready to lose their conduction and outer valence band electrons when exposed to the massfree electric radiation of the coil. This is simply demonstrated by the apparatus of FIG. **1**, in which the distal terminal of the secondary winding **6** of a Tesla coil having a primary winding **4** driven by a vibrator **2** is connected to the input of a full-wave voltage wave divider formed by diodes **8** & **10** and reservoir capacitors **12** & **14** (the same reference numerals are used for similar parts in subsequent Figures). If the rectifiers employed are nondoped, the coil appears to only charge the divider at the positive capacitance **10**, but if doped rectifiers are employed, the coil will be observed to charge both capacitances equally. Whereas positive ionizers can charge either doped or undoped dividers positively, no positive ionizer can charge a doped divider negatively, clearly demonstrating that the Tesla coil does not emit positive ions.

The basic demonstration that the output of a Tesla coil is not nonionizing electromagnetic radiation of high frequency, such as optical radiation, or of lower frequency, such as thermal photons, is also a simple one. Placement of a sensitive wide spectrum photoelectric cell (capable of detecting radiation to the limits of vacuum UV), wired in the traditional closed circuit manner from a battery supply, at any distance short of sparking from the distal terminal of the coil will show in the dark that the light output from the coil is negligible. This rules out optical radiation at high frequency. The demonstration that the sensible heat output from the Tesla coil is also negligible will be addressed below.

Our theory proposed the existence of physical processes whereby massfree electric radiation can be converted into electromagnetic radiation. Such a process is at work whenever massfree electric wave radiation interacts with electrons, such as those that remain in the valence bands of atoms. This massfree electric energy interacts with charge carriers, such as electrons, to confer on them an electrokinetic energy which they shed in the form of light whenever that electrokinetic energy is dissociated from those carriers (e.g. by deceleration, collision or friction processes). Such a process is at work to a negligible extent in the coil itself and its usual terminal capacitance, hence the faint glow that can be seen to issue from it, but it can also be greatly amplified in the form of a corona discharge by connecting a large area plate to the output of the secondary, as Tesla himself did in his own experiments, and thus by increasing the capacitance of the coil system. Now, what is interesting in this process is that, in the absence of virtually any I^2R losses at the plate, and if the plate thus introduced is bent at the edges so that it has no pointed edges, or if it is in the form of a bowl, or in any other manner that precludes sparking at edges and specially corners, and thus enhances the corona discharge, any electroscope, whether negatively or positively charged, now brought close to the plate will show a tendency to arrest its spontaneous discharge rate. One might say that this is simply the result obtained in a Faraday cage that disperses charge on its outside and insulates electrically its interior, and indeed if an electroscope is placed inside a Faraday cage no amount of Tesla radiation on the outside of that cage, save direct sparking, adversely affects the leakage or seepage rate of the electroscope. In fact, since the effect of such a cage can be shown to be that of, by itself, inducing arrest of either spontaneous electroscopic discharge, this effect simply remains or is magnified when the cage is bathed by Tesla radiation. However, a cage constitutes an electrically isolated environment, whereas a plate with or without curved or bent edges does not. Furthermore, the change observed in the properties of the output radiation from a Tesla coil when certain metal plates or surfaces are directly connected to the distal terminal of the secondary, takes place whilst the capacitance of the coil is increased by the connected plate, and thus the plate is an electrically active element of the circuit—and hence the opposite of an electrically isolated element.

For a long time we believed that the anomalous cathode reaction forces observed in autoelectronic discharges (atmospheric sparks, autogenous PAGD (pulsed abnormal glow discharge) and vacuum arc discharges) were exclusive to an autoelectronic emission mechanism prompted by a direct potential between discharging electrodes. Sparking driven by AC potentials could sustain the same forces, but their mutual cancellation over time would not deploy a net force. In this sense, when a large gold leaf connected directly to the ground (via a water pipe or any other suitable connection) or to another large area plate suspended at some height above the ground, is vertically placed at a sparking distance above the surface of another plate connected to the secondary of a Tesla coil, one would not expect the AC spark to sustain any net force across the gap between the gold leaf and the plate. In terms of cathode reaction forces, one would expect their cancellation to be simply brought about by the high frequency of the current alternation in the coil, as both leaf and plate would alternate between being the emitting cathode or the receiving anode. However, this is not what is observed—instead, the gold leaf **16** lifts away from the plate **18** (FIG. **2**). Connecting instead the suspended gold leaf to the coil terminal, and the bottom plate to the ground in the same manner as described above, also yields the same result.

Even more curious is the finding that this anomalous reaction force deployed by an alternate current of mass-bound charges in the arc, remains present when the sparking is prevented and instead the corona effect is enhanced (by employing a large plate connected to the distal pole of the secondary, and by employing a distance at which sparking ceases), as if the lift itself were the property of the corona underlying the spark channels and not the property per se of the autoelectronic emission mechanism.

By mounting directly the suspended leaf **16** (41 mg of hammered 99.9996% pure gold) at the end of a long dielectric rod **20** balanced at the center and placed on a light stand over an electronic balance **22**, we sought to determine the observed lift of the leaf as weight lost. Surprisingly, and despite the most apparent lifting motion of the leaf, the balance registered a substantial weight gain, indicating the addition of 1 to 5 mg weight (with the same 14 W input to the vibrator stage), independently of whether the leaf was connected to the terminal of the coil or instead to the earth ground via a water pipe. This suggested to us that, whether formed as a DC or AC spark channel, or whether in the form of a corona discharge, the electric gap develops an expansion force (exactly opposite to a Casimir force) on both electrodes, independently of their polarity, which force is responsible for the observed repulsion. Yet, this expansion goes hand in hand with an increase in their weight such that some other process is at work in that electric gap.

To examine this problem further, we assembled a different experiment where the gold leaf **16** was suspended between two large metal plates **18**, **24** placed 20 cm apart, and the leaf was not electrically connected to them or to any other circuit, while attached to the dielectric rod employed to suspend it over the electronic balance. Given that the leaf is suitably and equally spaced from both plates, there is no arcing between it and either plate. The obvious expectation is that, since the electric field bathing the leaf alternates at high frequency (measured in hundreds of kilohertz), and the corona from both electrodes should equalize and balance any electric wind, no lift should be observed. In fact, no lift is apparent, but a most curious observation is made: depending upon which orientation is employed for the plates, the gold leaf either gains or loses 4–6% of its weight. This gain or loss is registered for as long as the coil is on. If the top plate is grounded and the bottom one connected to the different terminal of the secondary, a gain in weight is observed (FIG. **3**). If the connections are reversed, an equal weight loss is registered (FIG. **4**).

Furthermore, in this last instance, if the grounded plate **24** is entirely removed (FIG. **5**), and only the top plate remains connected to the distal terminal of the secondary, the observed loss of weight continues to occur such that effectively this reaction can be obtained with unipolar electric fields of high frequency, and provides a unidirectional force which, once exerted upon metallic objects bathed by its field, can be made to oppose or favour gravity.

Now, these effects can be greatly magnified, in the order of 10-fold, if the same gold leaf is made part of a simple series floating electric circuit where the leaf functions as a large area plate, and is wired in series with a coil **26** which, for best results, should be wound so as to be of a length resonant with the secondary of the Tesla-type coil employed; and this coil is connected in turn to a point antenna **28** upwardly oriented (FIG. **6**). The entire floating circuit is mounted on the rod **20** and this in turn is mounted over the sensitive balance. If both plates are kept as in FIGS. **3** & **4**, the observed weight loss and weight gain respectively vary between 30 to 95% of the total weight of the leaf. Again the gain or loss of weight is registered for as long as the coil is on.

These anomalous findings suggested that whatever is the nature of the energy responsible for the force observed in that high frequency alternating current gap, any metallic object placed in that gap will experience a force repelling it from the electric ground. This force will be maximal if the gap frequency is tuned to the elementary or molecular structure of the metallic object. If the electric ground is placed opposite the actual plane of the earth ground, that force will act in the direction of gravity. If, instead, the electric ground and the earth ground are made to coincide on the same plane, that force will act opposite the direction of gravity, i.e. will repel the metallic object from the ground.

No such weight alteration was observed with solid dielectrics, for instance with polyethylene and other thermoplastic sheets.

These facts rule out the possibility of a hidden electrostatic attraction force acting between the plate connected to the different terminal of the secondary and the gold leaf. First off, such an attraction would be able to lift entirely the gold leaf, as is easily observed with the unipole of any electrostatic generator operating with a few milliwatts output with either negative or positive polarity; secondly, the same attraction, if it existed and were the product of an electric force, would surely be manifested independently from whether the experimental leaf was metallic or a dielectric (as again is observed with electrostatic generators).

The results suggest therefore that whenever a large plate is connected to a Tesla-type coil, it induces in surrounding matter that is not part of its own circuit, a directional thrust oriented opposite the electric ground and, if the latter coincides with the gravitational ground, a thrust oriented opposite free fall.

When this thrust is made to oppose gravity, we believe that its effect upon the gold leaf can be compared to the lifting power imparted to the water molecule when it transits from the liquid to the vapor state and which is associated with the increase in internal (or intrinsic) potential 'thermal' energy ΔU (See Halliday D & ResnickR (1978) "Physics", Vol. 1, section 22–8, p. 489). The "specific latent heat" of water (m*L) contains indeed both an expression for the sensible radiant thermal work involving volume and pressure relations ($W=P(V_V-V_L)$, where P=1 Atm, and V_V and V_L, respectively, are the molar volumes in the vapor and liquid phases), and an expression for a quantity of "latent" energy (ΔU) which is associated with the molecule in the more rarefied state. Hence, the relation for the latter with respect to water vapor:

$$\Delta U=(mL)-[P(V_V-V_L)]$$

We propose that likewise, if a very small portion of the energy of the massfree electric waves is indirectly transformed by massbound charge carriers on that plate into blackbody photons (once those charge carriers shed their electrokinetic energy), the greater portion of those waves are directly transformed in the space adjacent to that plate into the latent energy equivalent to ΔU for the atoms of the surrounding air, and so on, until this process itself is also occurring for the atoms of that gold leaf, thus inducing their nonelectrical weight loss and suggesting the existence of a nonthermal "antigravitokinetic" energy term heretofore unknown to mankind other than as "latent heat" or "internal potential energy".

From this viewpoint, the energy released by any Tesla-type coil to its surroundings would be tantamount to a radiative injection of "internal potential energy" which would confer on local gas molecules a weight cancellation (a cancellation of gravitational mass occurring in the absence of any cancellation of inertial mass—a process which the inventors theorize is explained by the neutralisation of elementary gravitons), and the same process would be equally at work for metallic solids but not dielectric solids.

Gold vapour also deploys a substantial intrinsic potential energy. With an enthalpy of vaporization on the order of H_v=324 kJ mol^{-1}, the molar volumetric work performed by gold vapor at atmospheric pressure at the temperature of vaporization T_v (2,856° C., i.e. 3129 degrees Kelvin) is:

$$W=P\Delta V_{V\text{-}L}=23.58 \text{ kJ mol}^{-1}$$

where $\Delta V_{V\text{-}L}=0.2327$ m^{-3}. The intrinsic potential energy of gold vapor is then given by:

$$\Delta U=H_v-W=300.4 \text{ kJ mol}^{-1}$$

i.e. 12.74 times greater than the volumetric work performed during the phase transition.

It is our contention that this intrinsic potential energy, associated with molecules as their "latent heat", has fine structure that in turn is altered if this energy is released from these molecules and fails to gain a "sensible" thermal form. What is suggested is that the fine structure of "latent heat" is not electromagnetic and obeys instead the molecular function:

$$\Delta U/N_A=\lambda_{n2}^2 cf_{n2}$$

where N_A is Avogadro's number, the wavelength denoted as λ_{n2} is the wavelength-equivalent of the mass of the molecule to which the "latent heat" is associated, obtained by a conversion method proposed in these inventors' theory, and the frequency term f is a nonelectromagnetic frequency term, specifically in this case a gravitational frequency function. Employing the conversion of Joules into m^3 sec^{-2} proposed by these inventors as being exactly 1 J=10N_Am^3 sec^{-2}, and putting the wavelength λ_{n2} down as the wavelength-equivalent of the mass of the gold atom, λ_{Au}, at 1.9698 m, that frequency term f_{n2} can be obtained as being equal to 2.6*10^{-3} sec^{-1}. According to the present inventors' theory, the wavefunction c constitutive of the fine structure of "latent heat" associated with molecules of matter, carries the same wavelength λ_{Au} and its frequency is given in the usual manner by c/λ_{Au}=1.52*10^8 sec^{-1}. The resultant frequency for the non-Planckian unit quantum of "latent energy" associated with each gold atom at the vaporization temperature is then obtained by the geometric mean of the two synchronous frequency terms:

$$[(c/\lambda_{Au})f_{n2}]^{0.5}=624 \text{ Hz}$$

However, this is the signature of that intrinsic potential energy when associated with that gold atom at its vaporization temperature. It is not the signature of the energy quantum itself if it is released from that molecule, nor prior to being absorbed (i.e. in transit), at that same temperature. The fine structure of the same non-Planckian "latent" energy quantum varies to encompass different determinations of the constituent wavelength and frequency functions. The basic relation for the determination of the wavelength of a "latent thermal" energy quantum not associated with matter, but corresponding to one that is, is:

$$\lambda_{n1}=[\Delta U/N_A)/c]^{0.666} \text{ meters}^{-0.333} \text{ seconds}^{0.666}$$

which gives 0.046478 m for the unbound equivalent of the "latent heat" unit quantum of vaporization associated with the gold atom at one atmosphere. The fine structure of the free quantum is still parallel, as given by:

$$\Delta U/N_A=\lambda_{n1}^2 cf_{n1}$$

but now notice how the frequency terms have changed value, with the f_{n1} function having the value 4.65 sec^{-1} and c/λ_{n1} yielding 6.48*10^9 sec^{-1}. The geometric mean of the superimposition of the two frequencies is then—

$$[(c/\lambda_{n1})f_{n1}]^{0.5}=173.7 \text{ KHz}$$

We contend that it is at this frequency that the atoms of gold vapor absorb "latent heat".

However, this is just the overall scenario of what happens at the temperature of vaporization of gold. But at room temperature (e.g. 293 degrees Kelvin), and with respect to processes where there is no sublimation of the atoms of that gold leaf under way (and indeed, once the coil is turned off, the leaf returns to its normal weight), one must infer to a different phase of matter what portion of "latent heat" energy, if any, do the atoms of gold hold in the solid phase lattice. Assuming the same proportionality between the "sensible" and "latent" thermal energy terms for atoms of gold at room temperature, where the unit thermal energy is N_A kT=2.436 kJ mol^{-1}, the gold atom could absorb up to 12.74 times, we speculate, the value of this "sensible" thermal energy, and thus hold N_A kT=31.053 kJ more energy in its own micro-atmosphere.

If this speculation is correct, and employing the above novel methodology, then the mean geometric frequency of the maximal "latent heat" energy quantum of a gold atom at room temperature would be 538 KHz (versus 174 KHz at the vaporization temperature), and once absorbed its mean frequency mode would abate to 201.5 Hz (versus 630 Hz once the atom has vaporized).

To test this hypothesis we employed two different Tesla-type coils having output frequencies of 200 KHz and 394 KHz. The circuit tested was that shown in FIG. **6**, and both coils were operated at 50 KV outputs. Whereas the former coil, closer to the 174 KHz marker, could only systematically produce 10–11 mg of weight cancellation in the gold leaf of the floating circuit, the second coil, closer to the speculated 538 KHz marker, could produce 15–35 mg of weight cancellation in the same gold leaf. The empirical results appear therefore to suggest that our speculation may well be a valid one.

The above-mentioned full wave divider (see FIG. **1**) can be easily coupled to our autogenous pulsed abnormal glow discharge technology as described in our U.S. Pat. No. 5,416,391 to form an alternative source of direct current, ultimately powered by Tesla waves, and such a drive can equally be applied to any other vacuum device that can sustain endogenous oscillatory discharges, whether in the PAGD regime or any other pulsatory regime. For the purposes of experimental and visual determination of power outputs from the divider in question, we have utilized either 2 Torr vacuum tubes operating in the high-current PAGD regime, or 20–100 Torr spark tubes requiring high voltages (2 to 10 KV) for their spark breakdown. As taught in the above U.S. Patent, the output from the full wave voltage divider can be assessed by the energy spent in driving the tube and the motor, whose rotary speed is proportional, within the limits chosen, to the power input.

Two separate sets of experiments set forth in Table I below showed that direct connection of the wave divider to the distal terminal of the coil (set constantly at 6 clicks on the vibrator stage) (FIG. **1**) or to the same terminal but across a large (2 or 3 square feet) plate **30** that increased the capacitance of the secondary (FIG. **7**), presented the same power output in either case (the effect of the plate is to lower the voltage of the output proportional to the increase in current). A substantial increase in power output through the divider is observed only when an identically wound Tesla coil is connected in reverse (FIG. **8**) with the non-common end of its winding **4** not connected, in order to obtain a condition of resonance, and this observed increase is further augmented by now interposing either of the metal plates **18**, **24** between the two chirally connected and identical coils (FIG. **9**). The increase in plate area appears to have the effect of increasing the output for as long as the plate is isolated between the two chiral image coils. Throughout these experiments the input power to the vibrator was fixed at 14 W (60 Hz AC).

TABLE 1

Status	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM
Expt A		
Tesla coil (TC) to divider	2.6	582.5 ± 3.9 (n = 4)
TC to inverted TC, to divider	4.4	621 7.6 (n = 4)
TC to 2 ft^2 plate, to inverted TC, to divider	5	775.25 ± 23.6 (n = 4)
Expt B		
Tesla coil (TC) to divider	2.2	613 ± 5.6 (n = 12)
TC to 3 ft^2 plate, to divider	2.3	605 ± 2.6 (n = 12)
TC to inverted TC, to divider	2.3	722 ± 5.7 (n = 12)
TC to 3 ft^2 plate, to inverted TC, to divider	4.2	877.6 ± 6.5 (n = 12)

In our loss of weight experiments described above, we noted that the phenomenon of weight loss by a metallic body placed in proximity of the coil output continued to be observed when only the plate connected to the distal pole of the secondary was retained. The leaf, although not part of the circuit of the secondary, could however be seen as part of a circuit for the capture of ambient radiant energy, specifically that generated by the coil and, as well, that also possibly picked up, in the process, from other ambient sources. To determine whether the last consideration is a possibility at all, or whether the energy picked up by an analogue of our metallic body or gold leaf in the experiments described above, is entirely a byproduct of the energy transmitted by the plate connected to the distal pole of the secondary, we next determined what would happen if the pick-up for the full wave-divider were placed not at the output from the secondary coil, but from an in all respects identical plate (the Receiver plate R, as opposed to the Transmitter plate T) placed a distance away from, and above, the first one. In other words, the gold leaf is replaced by a receiver plate, and this carries an attached test circuit identical to the test circuit employed to assess directly the coil output.

As shown in Table 2 below, the results of the experiment show that there is no loss of energy picked up at the R plate (FIG. **10**) when compared to the most favourable situation involving the plate **30** (FIG. **9**) interposed between the chirally connected coils. This observation is however not always the case. For best results one should employ iron, gold or silver plates placed parallel to the horizon, with the T plate underneath the R plate. In fact, if one employs instead aluminum plates and suspends these vertically, one can consistently register a loss of output at the divider when changing the divider input from the T to the R plates.

If however the plate R is connected in turn to a second identical coil, also wired in reverse, and this second coil in turn serves as input to the full wave divider (FIG. **11**), then a most curious occurrence takes place—the power output increases considerably (see Table 2), as if the divider circuit had undergone an energy injection not present at the source. Note that the circuits are in fact resonant, but the energy injection contributing nearly 60–66% (for both plate areas in the previous experiment) of the input that we refer to, is not caused by inductive resonance, since the effect of resonance can be ascribed to the set-up described in FIG. **9**. The distance between the plates, as well as their orientation with respect to the local horizon system of the observer also appear to matter, best results being achieved at optimal distances (e.g. for 2 square feet plates the best gap, at 43% RH and room temperature, was at least 6 inches).

TABLE 2

Status	T R distance	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM
$2\ ft^2$ plates			
R plate to inverted TC, to divider	3"	6.7	882 ± 17.5 (n = 4)

R plate to divider	8"	4.0	783.1 ± 11.3 (n = 12)
R plate to inverted TC, to divider	8"	5.1	1005.7 ± 6 (n = 12)

We tested the possibility that environmental heat produced by operation of the coil might be the source of the injected energy, the plate of the second system acting possibly as collector for the heat present in the gap. As it turned out, experiments showed repeatedly that in the gap between the T and R plates there was no significant thermal radiation propagating between one and the other. The more illustrative experiments are those in which we identified where the sensible thermal energy appears, and which involved coupling two cavities: the Transmitter-Receiver gap between plates T and R, and a Faraday cage enclosure **34** (see FIG. **12**). The first cavity appears to be much like that of a capacitor: the two identical parallel plates are surrounded by a thick dielectric insulator **32**, and a thermometer T**2** is inserted half-way through it. A thermometer T**1** is also affixed to the T plate, to read its temperature. The second cavity is a simple metal cage, also insulated, with a thermometer T**3** inserted 2 cm into its top. 2–4 cm above the top of the cage there is placed a fourth thermometer T**4**, within an insulated cylinder. If the TC is a source of thermal energy (e.g. IR radiation, microwaves, etc.) we would expect the T plate to be the hottest element from which, by radiation, thermal energy would reach the middle of the first cavity making the next thermometer T**2** second hottest, and that the third thermometer T**3** inside the second cavity, even if it might initially be slightly warmer than the other two, would, over time, become comparatively cooler than either one of the other two thermometers, despite the fact that the rising heat would still be seen to warm it up over time. One would expect a similar outcome for the fourth thermometer T**4**, above the cage. As shown by FIG. **13**, where only the temperature differences ($\Delta T^\circ - T_c^\circ$) between the experimental thermometers and the control thermometer reading the air temperature T_c° of the laboratory are shown, the surface of the T plate warms up by 0.1° C. at 3' after initiation of the run (closed squares), whereas in the space of the T/R gap a diminutive warming, by 0.05° C., is registered after 10' (open circles). Conversely, the temperature inside the cage, at the top (shaded circles) rises by 0.1° C. also by the third minute, and the temperature above the cage itself (shaded squares) rises by a much greater difference of 0.35° C., which remains stable after the eighth minute.

These results show that it is not sensible heat that radiates from the T plate. Rather, some other form of radiation traverses these cavities to generate sensible heat at their metallic boundaries, such that more heat is generated above the R plate (inside the cage) and again above the third plate, i.e. above the top of the cage, than is generated in the T/R gap, i.e. proximally to the T plate. This clearly shows that the Tesla coil is not a significant source of thermal radiation, and that sensible heat can be detected inside and atop the Faraday cage only as a further transformation of the radiant energy transmitted across the T/R cavity.

The same experiment also illustrates that, whatever is the nature of the additional environmental energy being injected at the surface of R plate (as shown by Table 2 results above), it is most likely not thermal radiation, at least not energy in the form of sensible heat. And whatever is the nature of this ambient radiant energy being mobilized by the electric radiant energy transmitted from the T plate, it can produce significant heat inside an enclosure contiguous with plate R.

Since we also know experimentally that this observation of an ambient energy injection at the R plate or R cage depends upon relative humidity, being most easily observable when the latter is low (<50% RH), and being virtually impossible to observe when air is saturated with water vapor, we can infer that water vapor is a good absorber of the electric massfree radiant energy emitted from the T plate. This strongly suggests that this absorption process is tantamount to increasing the potential intrinsic energy ΔU of the water vapor molecules adjacent to the T plate. In the absence of significant quantities of water vapor, when the atmosphere is dry, one may speculate that this absorption process is replaced by what one presumes is a parallel process involving the various gaseous molecules of air. However, either because the air molecules involve molecular species that readily give off this potential energy, as one might speculate is the case with molecular oxygen, hydrogen and nitrogen, or because the air molecules absorb far less "latent" energy (as appears to be the case with inert gases), and therefore there is more of it in the molecularly unbound state (as we explicitly propose as a possibility) and thus available for absorption by the appropriately tuned receiver, the increased ΔU of air molecules conferred by the absorption of the massfree electric radiation in the T/R gap is transferred to the R conductor together with the latent energy which those molecules already possessed before entering that gap. Hence the energy injection and its dependency upon the partial pressure of water vapor, which absconds instead with this "latent" energy and succeeds in withholding it from transmission to the R plate.

If the T/R gap can mobilize ambient energy which is neither electromagnetic nor thermal in nature, but which "latent" energy becomes injected into the divider circuit in electric form, the heat (i.e. sensible thermal energy) produced inside and atop the cage can also be mobilized electrically as input into the divider circuit. The obvious place to look for the emplacement of the cool junction that could convert sensible heat into electrokinetic energy of massbound charges is at the top of the cage, where it is warmest (See top curve of FIG. **13** in shaded squares). This is clearly observed from the results shown in Table 3 below, where the initial temperature difference between the top of the box and the T plate surface was 0.5° C., and the top of the box temperature rose by 0.2° C. after 2.5 minutes when the divider was connected at the junction, versus 0.35° C. when it was not (and the transmitter coil was on).

TABLE 3

Status 3 ft^2 plates	TR distance inches	Pulse rate PPS	Motor rotation RPM, M ± SEM(n = 12)
TC to T plate, to divider	NA	4.2	877.6 ± 6.5
R plate to inverted TC, to divider	6"	5.1	1009.2 ± 4
Top of naked R plate/cage to divider	6"	5.4	1047.1 ± 5.7
Top of insulated R plate/cage exposed to sun, to divider	6"	6.1	1072.4 ± 8.7

For the run performed with the naked R cage, the temperature directly above the top of the cage was 24.3° C., at the outset, versus the control room temperature of 23.9° C. For the run performed with the insulated R cage exposed directly to the sun at midday, on a cool and clear August day, the temperature directly above the top of the cage was 33° C., versus the control air temperature of 18.4° C. The temperature of the cool junction at the top of the cage was 31.9° C. while the run was performed.

It is apparent from the data of Table 3 how a second injection of energy has occurred in the apparatus. If, within the T/R gap, the energy injected appears to be on the order of absorption of "latent heat", at the top of the cage cavity, at the cool junction, the injection is one of radiant "sensible" heat. Moreover, this secondary energy addition could be further enhanced by placing strong insulation around the whole apparatus or the cage itself, and further so, by exposing the whole apparatus to solar radiation.

We next turned our attention to the T/R gap cavity with the intention of determining whether atmospheric conditions or vacua yield the same or different results. We could not, of course, test the same large area plates as have been employed for the studies undertaken at atmospheric pressures. For the present purpose we employed instead large area electrodes (ca 0.2 ft^2) made of high grade stainless steel or even aluminum. Preliminary results showed that these T/R gap tubes, when coupled to the divider circuit, yielded faster pulse rates in the secondary circuit when evacuated than at atmospheric pressure. The strength of the corona discharge also intensified, as it eventually became replaced by a normal glow discharge. For purposes of improved spatial capture of (1) the electric massfree energy radiated from the T electrode and (2) the non-radiant latent thermal energy mobilized by it to be collected electrically at the R plate, an axial cylindrical T electrode was inserted inside a larger concentric cylinder or between two common plates of large surface area (e.g. >100 cm^2) functioning as the R electrode(s), in a dielectric container suitable for evacuation (glass, polycarbonate), at a typical distance of at least 3 cm between electrodes, and the entire device was tested at different pressures. The secondary circuit connected downstream from the full wave divider was as shown in FIG. **14** (employing an autogenous pulsed abnormal glow discharge, or PAGD, converter circuit), with the PAGD reactor 36 set at 10 Torr (in light of the high-voltage input, which varied between 1500 and 3200V) and gave the results presented in Table 4 below. We should remark also that these pulses charged the charge pack CP through the coupling capacitors **38**, bridge rectifier **40** and reservoir capacitors **42**, and blocking diodes **44**, as expected from the prior art represented by our patents related to PAGD devices.

TABLE 4

T/R tube Pressure (Torr)	Pulse rate (PPS)
760	0.376
0.025	0.513

The effect of the vacuum in the T/R gap tube seems to be dual. By transforming the corona discharge into a normal glow discharge, it increases the local production of photons (probably associated to the formation and discharge of metastable states in the plasma), and at the same time, increases the pulse rate in the output circuit and thus, in all probability, the energy injected in the T/R gap cavity. But this did not yet permit us to confirm whether or not it is "latent heat" energy of the plasma molecules which is being tapped at the receiver plate, even if it be plausible in principle that plasmas may effect more efficient transfer of "latent heat" to tuned receivers than atmospheric gases.

The vacuum dependency of the pulse rate of the PAGD reactor employed as example in the secondary circuit downstream from the divider is also rather well marked, with the fastest pulse rates being registered at 1 Torr for the sample run shown in Table 5 below.

TABLE 5

T/R tube Pressure (Torr)	Pulse rate (PPS)	PAGD Reactor Pressure (Torr)	Voltage (across divider)
0.025	0.115	90	4.5 kV
0.025	0.1553	75	3.5 kV
0.025	0.183	60	3.3 kV
0.025	0.291	30	
0.025	0.513	15	1.6 kV
0.025	0.602	10	1.4 kV
0.025	2.9	2	0.53 kV
0.025	4.1	1	0.45 kV

It is worth noting here that the illustrated polarity of the wiring of the PAGD reactor tube, as shown in FIG. **14**, is best for purposes of sustaining regular autoelectronic emission at high voltage. The reverse configuration, with the center electrode negative and the plates positive favours instead heating of the cathode and a lapse into a normal glow discharge.

We tested a similar arrangement to that shown in FIG. **14** above, but with a PAGD motor circuit (see our U.S. Pat. No. 5,416,391). A split phase motor **44** replaces the rectifier and charge pack, and the PAGD reactor is operated at the same pressure of 15 Torr, as shown in FIG. **15**. The T/R gap tube tested had a longer plate distance (2"), with one plate now functioning as Transmitter and the other as Receiver. Note also the different wiring of the PAGD reactor. The results, as shown below in Table 6, present pulse per second (PPS) and motor revolutions per minute (RPM) curve trends that appear to be analogous and parallel to the well-known Paschen curves for breakdown voltage in vacuum—such that the T/R gap performs better either in the atmospheric corona discharge mode, or in the high vacuum normal glow discharge (NGD) mode, than in the low breakdown voltage range of the curve where the discharge forms a narrow channel and takes on the appearance of an "aurora" transitional region discharge (TRD).

TABLE 6

T/R tube Pressure (Torr)	Pulse rate (PPS)	Motor rotation (RPM), M ± SEM (n = 17)	Discharge Type
760	2.8	751.2 ± 7.1	Corona
100	2.1	611.5 ± 5.1	TRD
20	2.4	701.9 ± 4.6	TRD
0.006	2.8	748.4 ± 9.3	NGD
0.003	3.0	819.4 ± 6.3	NGD

These results suggest that plasmas with high lateral dispersion, i.e. formed over large electrode areas (e.g. corona and NGD plasmas) and thus devoid of pinch, are more likely to mobilize electrically the intrinsic potential energy of the molecular charges than pinch plasmas appear to be able to do (e.g. TRD plasmas). Apparently also, the greater the vacuum drawn from the T/R gap cavity, the more efficient does the transfer of this intrinsic potential energy, ie the massbound latent heat, to the electrokinetic energy of the charges circulating in the receiver circuit become. At about $6*10^{-2}$ Torr, this transfer in vacuo is comparable to that observed under atmospheric conditions and thus for a much greater density of molecules.

We investigated whether it Is possible to tap the latent heat energy of water molecules. It is possible that in the vapour phase they can effectively hold onto their latent energy—but once closely packed in liquid phase could they give off some of it? To test this hypothesis we immersed the T/R gap in a glass water tank. The motor employed for these tests was a high-speed 2 phase drag-cup motor (see FIG. **18** and associated description), wired in split-phase with two identical phase windings capacitatively balanced, and the galvanized iron plates had one foot square areas. The results are shown in Table 7 below, and clearly indicate that it is possible to tap—within the T/R cavity—the ‘latent heat’ of water in the liquid phase. As observed, immersion of the T/R cavity in water increased the motor output speed 22% (=12,117/9888)*100). This corresponds to a 50% increase in power output, from 18 W at 9888 rpm to 27 W at 12,117 rpm:

TABLE 7

	Pulse rate PPS	Motor rotation RPM M ± SEM	T/R distance cm
Direct from TC	0.3	8076 ± 89.3	NA
TC to T plate	0.5	9888 ± 78.7	NA
R plate	2.75	12117 ± 29.8	30
R plate	2.9	12203 ± 55.9	60

Thus the use of ion-containing water or other ion-containing aqueous liquid in the cavity promotes long distance propagation and a greater injection of latent and thermal energies in the receiver circuit. Such a result is not achieved if the cavity is filled with deionised water.

The preceding results lead therefore to the design of a presently preferred apparatus, based on these findings, for the conversion of massfree electric energy, “latent heat” energy and “sensible” heat energy into conventional electric energy, as shown in FIG. **16**, which integrates all the separate findings and improvements. The winding **6** of the Tesla coil at the bottom is driven in the usual manner employing a vibrator stage **2** to pulse the primary coil **4**. The distal pole of the secondary **6** is then connected to a circular metal plate T which is one end of an evacuated cylindrical cavity, connected to a vacuum pump or sealed at a desired pressure, or which forms a still containing water or other aqueous solution or liquid. This cavity constitutes the transmitter/receiver gap, and is therefore bounded by a dielectric envelope and wall structure **32**, with the circular receiver plate R as its top surface. In turn this plate R serves as the base of a conical Faraday cage **34**, preferably air-tight and at atmospheric pressure, but which could also be subject to evacuation, which conical structure carries at its apex provisions for a cold junction **45** and any possible enhancement of the same junction by surface application of different metallic conductors that may optimize the Peltier-Seebeck effect. The output from the cold junction where sensible thermal energy is added to the electrokinetic energy of charge carriers, is also the input to the distal end of the winding **6** of the chiral coil arrangement that sustains resonant capture of all three energy flows ((1) massfree electric waves of a longitudinal nature, (2) true “latent heat” or the intrinsic (thermal) potential energy, and (3) the thermokinetic energy of molecules, (i.e. “sensible” heat) and, placed in series with the input of the full wave divider **8**, **10**, feeds the circuit output from the series capacitors **12**, **14** grounded at their common tap. In the T/R gap, the transmitted electric longitudinal wave energy is captured along with any intrinsic potential energy shed by molecules caught in the field. Within the R element, expanded into an enclosure that guides “sensible” radiant heat, the latter is generated and then recaptured at the cold junction.

The apparatus consisting of the cylindrical T/R gap cavity and the contiguous conical cage is then preferably finished in gloss white and cylindrically enveloped within a matte black container **46** by effective thermal insulation **48**, the latter terminating at the height of the bottom disc T. Apparatus (not shown) may be provided to move the plate T vertically to adjust the T/R gap.

Another alternative embodiment of the apparatus is shown in FIG. **17**. Here the circuit driving the apparatus is as we have set forth in our prior patents, which employs an autogenous pulsed abnormal glow discharge tube **50** in the configuration shown, supplied by a battery pack DP through blocking diodes **52** and an RC circuit formed by resistor **54** and capacitor **56** to drive the primary 2 of a first Tesla coil to obtain at the distal pole of the secondary **6** the energy to be injected to plate T in the form of a central electrode of a coaxial vacuum chamber (sealed or not), of which the cylindrical metallic envelope forms the receiver plate R, the latter being placed centrally inside the conical cage **34** and contiguous with its walls and base. The top and bottom of the coaxial chamber carries suitable insulating discs, preferably with O-ring type fittings. Again, the apparatus is enclosed in insulation within a cylindrical container **46**, and the input into the capture circuit driven from the full wave divider is taken from the cold junction **45** at the apex of the air-tight cage. The output circuit is similar to that of FIG. **15**.

We have found however that even when the component values in the motor driver and motor circuits are carefully selected so that these circuits are co-resonant with the damped wave (DW) component of the motor driver pulses, the motor power output falls well short of that which should theoretically be attainable. In an endeavour to meet this problem, we replaced the squirrel cage type induction motor **44** by a drag cup motor of type KS 8624 from Western Electric in the expectation that the low inertia non-magnetic rotor would allow better response to the DW component. This motor is similar to one of the types used by Reich in his experiments. Although results were much improved they still fell short of expectations. Replacement of this motor by an inertially damped motor of type KS 9303, also from Western Electric, provided much better results as discussed below.

Fundamentally, the difficulties we encountered stemmed from the inability of motor couplings to respond efficiently and smoothly, and at the same time, to the pulse and wave components of DW impulses: that is, simultaneously to the high-intensity peak current pulses (the front end event), the DC-like component, and to the damped wave trains these cause, i.e. the pulse tails (or back end event) or AC-like component. This difficulty is present even when we just seek to run induction motors from the DW impulses of a Tesla coil, the very difficulty that led Tesla to abandon his project of driving a nonferromagnetic disc rotor mounted on an iron core bar stator with damped waves.

We believe that the key to the capture of the massfree energy flux output in electric form by Tesla transmitters, including any injected latent or thermal energy that have undergone conversion into electrical energy is to employ the tuned, unipolar, Y-fed, PAGD-plasma pulser driven split-phase motor drive we have invented (U.S. Pat. No. 5,416,391) in conjunction with an inertially damped AC servomotor-generator (see FIG. **18**): this has a motor shaft **64** which couples a drag-cup motor rotor **60**, preferably of aluminum, silver, gold or molybdenum, directly to a drag-cup generator rotor **62** that drives a permanent magnet (PM) flywheel **66**, freely rotatable in bearings **67**, that provides inertial damping. The shaft **64**, journalled by bearings **61** in the casing of the motor **44**, provides a power output through optional gearing **68**. The phase windings of the motor **44** are wound on a stator core **70** having concentric elements between which the rotor or cup **60** rotates. This structure makes it ideal for the capture of the DW impulses, whether sourced in the transmitter, amplified in the T/R cavity or sourced in the plasma pulser, all in synchrony. Effectively the motor couples the damping action of the drag-cup sleeve motor rotor, which action, as we have already found for the KS-8624 motors, is quite effective at absorbing the front-end DC-like event, with the inertial damping of the PM flywheel upon the drag-cup sleeve generator rotor, that in turn is quite efficient at absorbing the back-end AC-like wavetrain event.

The KS-9154 motor used by Reich was not an inertial damped AC drag-cup servomotor-generator. Had Reich succeeded in overcoming the limitations of his 2-phase OR Motor solution, as we have now shown it is possible to do—by applying the Function Y circuit to the PAGD split-phase motor drive which we invented, his motor would have suffered the same limitations which we encountered with the KS 8624 motor.

Any motor, by itself, has an internal or inherent damping whereby the acceleration only vanishes when the rotor is running at constant speed. For motors that operate on the basis of the drag principle, where the asynchronous slip is actually constitutive of the motor action, by inducing eddy currents in the rotor, the inherent damping is always more pronounced than for other induction motors. The damping or braking torque is produced when a constant current flows through a rotating drag disc or cup.

Aside from this inherent braking, dampers can also be applied to servomotors to further stabilize their rotation. They absorb energy, and the power output and torque of the motor is thereby reduced. Optimal operation of servomotors requires both rapid response on the part of the rotor to changes in the variable or control phase, and a stable response that is free from oscillation, cogging and overshooting. The rapid response is assured by employing low inertia rotors, such as drag-cups or cast alloy squirrel cages, and the overshooting and oscillation are reduced to a minimum by damping or a retarding torque that increases with increasing motor speed. Typically, in a viscous-damped servomotor, the damper is a drag-cup generator mounted rigidly on the shaft of the motor rotor, and the generator drag-cup rotates against the stator field of a static permanent magnet field. The generator develops a retarding torque directly proportional to speed, and the energy absorbed by the damper is proportional to speed squared. The damping can be adjusted and, as it increases, the same amount of input power yields lower torque and motor speeds. Inertial-damped servomotors differ from viscous damped motors in that the permanent magnet stator of the drag-cup generator is now mounted in its own bearings, either in the motor shaft or on a separate aligned shaft, forming a high-inertia flywheel. This means that, whereas the motor rotor always experiences a viscous damping in viscous-damped servomotors, in inertial-damped servomotors the drag cup motor rotor only experiences a viscous damping while accelerating the flywheel, with the damping torque always opposing any change in rotor speed. Once the flywheel rotates synchronously with the rotor, all damping ceases. Note that this viscous damping is carried out via the coupling of the drag-cup generator rotor, rigidly affixed to the motor rotor, to the PM flywheel, so that their relative motion generates the viscous torque proportional to the relative velocity. Use of drag-cup sleeve rotors in inertially damped servomotors was largely supplanted by squirrel cage rotors once the latter became produced as cast alloy rotors. Since inertially damped motors can be used in open and closed-loop servo applications, and present better stability—even in the presence of nonlinearities—and higher velocity characteristics than other induction motors do (Diamond, A (1965) "Inertially damped servo motors, performance analysis", Electro-Technology, 7:28–32.), they have been employed in antenna tracking systems, stable inertial-guidance platforms, analog to digital converters, tachometers and torque tables. The typical operation of an inertially damped servomotor is as follows: with the reference phase fully excited, the motor rotor—fixedly linked to the generator rotor, as well as the flywheel, remain immobile; once power is applied to the control phase, the motor rotor immediately responds but the flywheel remains at rest. However, as the drag-cup generator **62** is forced to move through the permanent magnetic field of the flywheel, it creates a drag torque that slows down the attached motor rotor proportionally to the acceleration that it imparts to the flywheel that it now sets into motion, thus creating the viscous damper. As the flywheel accelerates, the relative speed of the motor with respect to the flywheel, as well as the damping torque, decrease until both motor and flywheel rotate synchronously and no damping torque is exercised—at which point the drag on the motor cup exerted by the generator cup is negligible. The KS-9303 motor is an inertial damped servomotor but is differentiated with respect to other inertially damped motors, in that (1) it employs a drag-cup sleeve motor rotor made of aluminum, very much like that of the KS-8624, but with slightly altered dimensions and with a shaft extension for the drag-cup copper generator rotor, and (2) the moving flywheel structure was journalled on a separate, fixed shaft, as already described with reference to FIG. **18**. Now, in principle, even application of minimal damping decreases motor efficiency, resulting in diminished torque and speed. Whether the inertial-damped motor has a drag-cup rotor, a sleeve rotor or a squirrel cage rotor, the damping increases the rotor slip. Laithwaite considers drag-cup motors as being "dynamically inferior to their cage counterparts" (Laithwaite, ER

(1957) "Induction machines for special purposes", London, England, p. 323.). If we now add a viscous damping and retarding torque, we should not be able to get much more than a 55% efficiency in the best of conditions. On the other hand, the inertial damping arrangement described will only abstract or supply energy when the motor rotor is accelerating or decelerating relative to the flywheel.

These drag-cup motors, whether inertially damped or not, develop a constant torque at constant rpm for a given supply frequency and a suitable phase shift capacitance. For each frequency the motors respond to, there is an optimum resonant split-phase capacitance, but other values nearby are still suited for operation, and for each value of capacitance, there is an optimal frequency the motors respond to. For example the KS-8624 motor responds best at 450 Hz when a 1 μF capacitance is employed, responds best at 250 Hz when a capacitance of 10 μF is employed, and responds best at 60 Hz, when a capacitance of 100 μF is employed. As the capacitance increases, the resonant CW frequency of the motor is displaced to lower values. If we fix the capacitance at a value (e.g. 10 μF) suitable for testing the frequency response at a fixed voltage of 12 VAC, the observed result for both the KS-8624 and KS-9303 motors show a response distribution of the motor rotary velocity that has an identical peak at 250 Hz for both motors, with the response decreasing to zero smoothly on both sides of the peak. These results indicate that, when wired as a split-phase motor, the motor rotary velocity varies not as a function of voltage or current, but as a function of frequency when the phase-splitting capacitance is fixed within a suitable range, there being an optimal frequency mode for each value of suitable capacitance, with lower values of capacitance favouring higher frequency modes. For a given frequency and capacitance, the motor rotary velocity remains essentially constant and independent from voltage and current input, and thus at a plateau. Torque, in the same circuit arrangement, follows exactly the same pattern as rotary velocity, as a function of input frequency at a fixed potential. Torque is linearly proportional to rpm in these motors when they are split-phase wired, and rpm linearly proportional to CW frequency, which makes them ideal for experimentation and determination of power output computations. Moreover, since these are drag machines, the slip itself determines the rotor currents and these are susceptible of tuning such that their retardation and relative position in the field can find resonant modes for varying CW frequency and capacitance.

In the circuit of FIG. **17** when using the KS 9303 motor, the inertial damping of the flywheel coupling retards the motor rotor currents sufficiently to allow them to build up torque, with the entire motor assembly serving as the preferred sink for all of the energy, massfree and massbound, captured by the receiving coil circuit with a drawing action established by the motor on the circuit, and providing satisfactory absorption by an inertial damper of the combined, synchronized, damped wave impulses, those occurring at a low frequency as a result of the firing of the PAGD reactor, and those occurring at a higher superimposed frequency—sourced in the transmitter circuit and picked-up by the receiver plate and coil. The action of each DW impulse train itself comports two different events, the DC-like auto-electronic-like discontinuity that sets the motor into action and initiates the rotor currents, and the AC-like damped wavetrain that supports the consistency of those rotors. The concentration of current required to kickstart the motor is provided by the DW impulses of the PAGD reactor, whereas, once the motor is in motion, and particularly, once it is stabilized by the flywheel, the cumulative action of the higher frequency DW impulses makes itself felt by accelerating the rotor to an optimum rotary velocity.

For the next series of tests we employed the basic circuit diagram of the improved motor shown in FIG. **19**. The transmission station is the typical Tesla transmitter with a line-fed, 60 Hz vibrator stage. At the line input to the first stage, we place a calibrated AC wattmeter (Weston Model 432), and a Beckman 330B rms ammeter in series with the hot lead, we set the vibrator stage for 41 clicks, consuming between 28.5 and 35 W, as depending upon circumstances yet to be narrated. This consumption was confirmed by driving the coil from an inverter powered by a 12 volt battery. The inverter consumes 2.16 watts, and is 90% efficient. The total consumption from the battery was 42 watts (12V at 3.5 A); once the 2.16 watts is deducted and the efficiency taken into account, we obtain the same 36 W (vibrator stage at max, i.e. 47 clicks, in this experiment). The T/R gap is adjusted to 3", and 2 square ft plates are employed. Transmitter and receiver coils are tuned, and so are the plate capacitances, to 250 kHz, also the capacitances of the Function Y circuit connected at the output of the receiving coil. The rectified voltage and current generated by the transmitter secondary and by the transmitter plate was ascertained with a coil-tuned wave-divider (Function Y) circuit by loading it with different resistive values. The results constitute a measure of the massbound electrical power output directly from the transmitter apparatus. The same method was employed to ascertain the voltage, current and power of the massbound charges circulating in the receiving plate and coil circuit. The results are shown in Table 8 below:

TABLE 8

Massbound currents rectified by Function Y at the output of the Tesla transmitter, transmitter plate and receiver plate, as a function of the bleeding resistance employed in each of the function Y arms

	VDC (kilovolts)	ADC (amp)	WDC (watts)	R/arm (Mohm)
Direct from 20°	42–50	$3*10^{-5}$	1.26–1.5	500
From 2° (T) plate	26	$2*10^{-5}$	0.52	500
From 2° (R) plate	15.1	$1.25*10^{-5}$	0.189	500
Direct from 2°	20.4	$3.4*10^{-4}$	6.936	50
From 2° (T) plate	15.2	$2.4*10^{-4}$	3.648	50
From 2° (R) plate	9	$1.2*10^{-4}$	1.08	50
Direct from 2°	3.3	$1.75*10^{-3}$	5.775	1
From 2° (T) plate	3.5	$2*10^{-3}$	7.0	1
From 2° (R) plate	2.95	$1.6*10^{-3}$	4.72	1

The results indicate that the highest massbound power assembled by the secondary transmitter circuit does not exceed 7 watts—and this is directly output from the secondary **26** when the load is 50 Mohm, or from the transmitter plate when the load is 1 Mohm. The massbound electric power emulated by the receiving circuit (plate, coil and Function Y without the plasma pulser circuitry) never exceeds the massbound electric power output directly by the transmitter, and peaks when the resistive load value (1 Mohm) approaches the pre-breakdown resistance range of the vacuum tube, at 4.72 W. These findings then indicate that when the transmitter circuit is consuming a maximum of 35 W, a typical output from the secondary of the transmitter is 7 W, and at 3" of distance within the proximal field of the latter, the pick-up by a tuned receiver will be on the order of 5 W of massbound current duplicated within the receiving coil. The loss in the first stage is therefore on the order of sevenfold. Continuing with the description of the circuit of FIG. **19**, a 128 cm^2 plate area, 6 cm gap PAGD reactor is employed, connected as described in our prior art to a high-vacuum rotary pump (Correa, P & Correa, A (1995) "Energy conversion system", USPTO U.S. Pat. No. 5,449, 989.). Pressure readings were obtained with a thermocouple gauge during the operational runs. The KS-9303 motors to be tested are then connected to the PAGD reactor in the usual capacitatively-coupled, inverter fashion described in our prior art (Correa, P & Correa, A (1995) "Electromechanical transduction of plasma pulses", USPTO U.S. Pat. No. 5,416, 391.). Their rpm is detected by a stroboscopic tachometer and fed to a Mac Performa 6400 running a motor algorithm program calculating the power output. Motor measurements were made at five minutes into each run for the unloaded motors, and at ten minutes for the inertially damped motors. All experiments were carried out in the same work session. The experimental determination of the continuous rotary power output as a function of the reactor pulse rate confirmed that the improved circuit develops maximum rotary capture of the massfree energy in the receiver circuit at the lowest rates of pulsation, just as we have previously found for the conversion system of U.S. Pat. No. 5,449,989. Furthermore, the data showed that even motors of type KS-8624 are able to output power mechanically in excess of the massbound power output by the transmitter (7 W) or captured by the receiver (5 to a max of 7 W), once the PAGD rate decreases to 1.5 PPS. Such an anomaly can only be explained by the system having become able to begin capturing the massfree energy flux in the receiver circuit that we know already is output by the transmitter circuit. But this excess mechanical power is still, and clearly so, less than the power input into the transmitter. It represents a power gain with respect to the secondary, but a loss with respect to the primary. The full breadth of the capture of the massfree electric energy flux circulating in the receiver circuit is not seen until the motors are resonantly loaded because they are inertially damped.

The KS-9303 motors, once inertially damped, and thus loaded, are able to to recover enough power from the massfree energy field to develop a mechanical power, not just greatly in excess of the massbound power of the secondary, but also greatly in excess of the massbound power input to the vibrator stage and the primary, at 28 to 35 W. Once the pulse rate approaches the same 1.5 PPS marker, mechanical power in excess of the massbound electric power input to the primary becomes evident, peaking at nearly three times that input. In fact, the highest output recorded was also obtained with the lowest input to the transmitter circuit, the highest exact coefficient observed in this experiment being 100.8 W/28 W=3.6. Furthermore, with respect to the secondary massbound output, the same mechanical rotary output represents a much greater overunity coefficient of performance, on the order of 14.4 times greater. This is at least partly the result of the receiver and motor capture of the massfree electric energy output by the transmitter, and may be partly the result of massfree energy engrafted by the PAGD regime in the PAGD reactor. Reviewing the mechanical power output results as a function of increasing vacuum in the PAGD reactor and at different output power levels, any motor performance below the 5–7 W limit of the traditional massbound output power of the secondary represents an output mechanical power loss with respect to both the massbound secondary output and the massbound primary input. All the results for pressures down to 0.03 Torr fall in this category, and thus represent a very inefficient coupling to the PAGD regime. Any motor performance between 7 W and 28–35 W represent a loss with respect to the electrical power input to the transmitter system, but a net gain of power with respect to the massbound secondary power output. None of the non-inertially damped motors tested were able to perform outside of this area, under the test conditions. With more efficient primary to secondary couplings in the transmitter station, however, one could advantageously employ these motors alone to extract some of the massfree power of the secondary or to operate them in enclosed vessels without conventional external electrical connections. To reach satisfactory levels of recovery of massfree energy, one must dampen the superimposed DW impulses. Hence, all results showing outputs in excess of 35 W were obtained using the inertially damped KS-9303 motors, and represent a net overunity power gain over both the power input to the primary and the massbound power output by the secondary, or the massbound power emulated by the receiver circuitry. This happens when the PAGD pulse rate falls to 2 PPS, with the rotary power output steeply increasing as the rate falls to 1 PPS.

One of the interesting features of the motor circuitry we have proposed is that it can operate with pulsed plasmas in both the TRD and the AGD regions, the least efficient response occurring in the NGD region near the Paschen minimum. One might think that the voltage depression would allow increased current intensity supplied to the motors, but in fact that is not observed, with the flashing of the NGD yielding erratic oscillations and low values of current. In keeping with the notion that the TRD plasma is mainly composed of lagging positive ions, whereas the PAGD plasma is mostly an electron plasma, the observed direction of rotation of the motors is opposite in the TRD region to that of the AGD region. The NGD region therefore marks the depression where the velocity vectors change direction. In the second or PAGD region, motor operation is very quiet, unlike what is observed in the TRD region.

Part and parcel of the tuning of the circuit components is the selection of the optimum capacitances employed to couple the PAGD reactor to the motor circuit and split the phase to feed the auxiliary winding of the motor. We have experimented with capacitances ranging from 0.5 to 100 μF, and found that best results—for the specific circuit in question (including the characteristics of the transmission)—were such that the optimal value of the PAGD coupling capacitance lay near 4 pF, and the phase splitting capacitance, near 1 to 4 μF, depending upon weather conditions—in good weather days lower capacitance values can be implemented, and in bad weather days higher capacitances are needed. For ease of comparison in demonstrating the need to tune the circuit by employing optimal capacitances in those two couplings (reactor to motor, and motor phase coupling), we employed the same capacitances in both circuit locations. A comparison of tests using 1 and 4 μF values shows the difference caused by changing those capacitances from their optimal value: across all discharge regions of the pressure range that was examined, the four motors tested operating with greater motor speeds when the capacitances are set to 4 μF rather than to 1 μF. The less efficient performance obtained with 1 μF capacitances fits the inverse correlation of pulse power with increasing pulse frequency, such as we have found for the PAGD regime. This is made evident by a comparison of rpm versus pulse rate for the two capacitance values being considered. They demonstrate the higher pulse rates observed with the lower capacitance, that correlate with the slower motor speeds, and result in lower efficiency of the motor response. The results equally indicate that low capacitance values increase the pulse rate, but if this increase is out of tune with the rest of the circuit values, it results in power waste because it imposes a rate that is not optimal.

We have also experimentally determined that the efficiency of the system is affected by external weather conditions, higher efficiencies being noted on a fine bright day than under poor weather conditions even though the apparatus is not exposed to such conditions. This may reflect a diminution under poor weather conditions of latent massfree energy that can be taken up by the system.

The observed high efficiency of circuits including inertially damped motors indicates that the phenomenon does not reduce to a mere optimal capture of DC-like pulses produced by the reactor in what is essentially an AC motor circuit. Effectively, the pulsed plasma discharge deploys a front-end, DC-like pulse, or discontinuity, but this is followed by an AC-like damped wave of a characteristic frequency (having a half-cycle periodicity identical to that of the front-end pulse) to which the motor circuit also responds. Moreover, the massfree electric radiation from the transmitter circuit itself induces—in the receiver antenna, coil and circuit, and in the reactor discharge itself—the train of finer damped wave impulses responsible, after conversion through the wave-divider, for the massbound rectified current that is employed to charge the plasma reactor to begin with. Serving as trigger of the plasma discharges in the reactor are the DW impulses circulating in the receiver circuit, such that the two different lines of DW impulses, in the receiver circuit (for example 120 PPS for the pulses and 154 kHz for the waves) and from the reactor, are synchronized by interpolated coincidences, since their pulse and wave frequencies are different. Ideally, these two superimposed DW frequencies are harmonics or made identical. The receiver stage involves capture of the massfree electric energy received from the transmitter, duplication of the massbound current in the receiver coil, and injection of latent and sensible thermal energy in the T/R gap cavity that augments the emulated massbound current. The massbound current is employed to charge the wave-divider capacitance bridge and therefore the reactor. In turn, the plasma pulses from the reactor are superimposed with the DW impulses from the receiving coil, and together they are coupled to the split-phase motor drive. Hence the first receiver stage employs the totality of the energy captured in the T/R gap cavity-massfree electric energy transmitted by the T plate, latent and sensible thermal energy injected at the surface of the R plate—and produces in the receiving coil a massbound current comparable to that assembled in the transmitter coil by the action of the primary. The massbound current is stored in the wave-divider bridge and used to drive the plasma reactor in the PAGD region. Subsequently, the autogenous disruptive discharge that employs a substantial electron plasma generates both a concentrated, intense flux of massbound charges in the output circuit, and a massfree oscillation of its own. The damped motor is therefore fed directly with (1) the intense massbound current output from the reactor; (2) the pulse and wave components of the massfree electric energy captured by the receiver plate and coil (and matched by conduction through the earth), and which are gated through the wave-divider and the reactor for the duration of the PAGD channel; and (3) any massfree latent energy taken up from the vacuum by the PAGD event. Once the motor is set into motion, and is resonantly loaded with an inertial damper, we believe that it will also respond to the much weaker DW impulses captured by the receiver, since these impulses encompass both a DC-like front end—further enhanced by analytic separation through the wave-divider—and a damped wave at 154 kHz. Essentially the DW impulses that are ultimately sourced in the transmitter -and received unipolarly through the T/R gap—have sufficient DC-like potential (plus all the other requisite physical characteristics, such as frequency) to contribute directly to the motor response, once the motor has gained substantial speed (for they lack the current to set it into motion, one of the contributions from the plasma pulser). This is the case, provided that the motor itself is suited for absorption of both DC-like pulses and AC-like damped waves, which is precisely the case with motors of the type shown in FIG. **18** since the inertia of the flywheel is overcome through homopolar absorption of the damped oscillations simultaneously in the motor drag-cup rotor and in the generator drag-cup rotor.

We also tested these inertially damped motors in the traditional DC power supply-driven PAGD circuit we have taught in our previous patents, that is, circuits with an overt HV DC power source, and thus in the absence of any Function Y circuit or transmitter circuit. Here then, only the DW impulses generated by the PAGD reactor can account for the motor response. The tube employed (A31) had an area of 256 cm^2, and a gap distance of 4 cm. Coupling capacitances employed were 4 μF for the inverter coupling, and 1 μF for the split phase motor coupling. The DC power supply delivered up to 1 ampere of current between 150 and 1,000 VDC, and the ballast resistor was adjusted to 215 ohms. Having determined the basic physical characteristics of the reactor's behaviour in the circuit under consideration, we conducted our experiment in the PAGD region. We chose a pressure of 0.6 Torr, just off from the Paschen minimum, as we intended to benefit from the lower sustaining voltage that it affords. The experiment basically consisted of increasing the sustaining voltage at this fixed pressure in the PAGD regime, and measuring the diverse physical parameters of the circuit and motor response in order to ultimately ascertain the difference between the input electric DC power and the output mechanical rotary power. We first looked at how the motor rpm response varied as a function of the sustaining voltage (V_s): the results illustrate the importance of starting close to the Paschen minimum in the pressure scale, since the KS-9303 motors reach plateau response (at 17,000 rpm) when the reactor output voltage nears 450V. Any further increase in potential is simply wasted. Likewise, the same happened when we measured motor speed as a function of increasing peak DC current, plateau response being reached at 0.1 ADC. Again, any further increase in current is wasted. Essentially then, the optimal power input to the reactor when the latter's output is coupled to the motor, lies around 45 watts. This is a typical expenditure in driving a PAGD reactor. As for pulse rate we once again find a motor response that is frequency proportional in the low frequency range, between 10 and 40 PPS (all pulse rates now refer solely to PAGDs per sec), but once rates of >40 PPS are reached, the response of the motor also reaches a plateau. The observed increment in speed from 40 to 60 PPS translates only into an increase of 1,000 RPM, from 16,000 to 17,000 RPM. So, we can place the optimal PAGD rate at ca 40 PPS. The DC electric power input to drive the PAGD reactor was next compared to the rotary mechanical power output by the inertially loaded motor, driven in turn by the reactor. This comparison was first carried out with respect to the PAGD rates. The motor response far exceeds the conventional input power, indicating that the whole system can be tuned to resonance such that optimal power capture inside the reactor takes place, the critical limit rate lying at around 60 PPS, when the motor response is firmly within the pulse response plateau. At this juncture, the break-even efficiency for the measured rates of energy flux over time reach 700% (overunity coefficient of 7), in keeping with the observations and the values we have made in the PAGD conversion system. In the proportional part of the curve, before the plateau is reached, even greater rates of break-even efficiency—up to >1,000% were registered. These results constitute the first time we have been able to confirm the presence of output energy in excess of break-even over conventional mass-bound energy input in the PAGD inverter system, and the results are comparable to what we have observed and previously reported for the PAGD converter system. At pulse rates greater than 60 PPS a greater input power results in decreased efficiency, also translated into a noticeable heating of the reactor and motor. And this is all the more remarkable as experiments we have conducted with inductive tuning of PAGD reactors, or employing PAGD reactors as replacements for the primaries of Tesla coil assemblies, and still, more recently, with the PAGD inverter circuit driving motors, have all shown that it is possible to operate these reactors with minimal mirroring and heating, preserving essentially the cold-cathode conditions and yet focusing the plasma column so that deposition on the insulator is negligible. It appears that above a certain threshold of optimal efficiency, surplus input energy is just dissipated thermally by both the reactor and the motors.

It should be understood that the above described embodiments are merely exemplary of our invention, and are, with the exception of the embodiments of FIGS. **16**–**19** designed primarily to verify aspects of the basis of the invention. It should also be understood that in each of these embodiments, the transmitter portion may be omitted if an external or natural source of Tesla waves is available, provided that the receiver is tuned to the massfree radiation mode of the source. For example if solar radiation is available in which the massfree component has not interacted with the earth's atmosphere (as in space applications), the receiver is tuned to the voltage wave of the massfree radiation sourced in the sun, e.g. by using a Tesla coil in the receiver constructed to have an appropriate voltage wave close to the 51.1 kV characteristic of such radiation.

We claim:

1. A device for the conversion of massfree radiation into electrical or electrokinetic energy comprising a transmitter of massfree electrical radiation having a damped wave component, a receiver of such radiation tuned to resonance with the damped wave frequency of the transmitter, a co-resonant output circuit coupled into and extracting electrical or electrokinetic energy from the receiver, and at least one of a transmission cavity between the transmitter and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed glow discharge device incorporated in the co-resonant output circuit.

2. A device according to claim **1**, wherein the output circuit comprises a full wave rectifier presenting a capacitance to the receiver.

3. A device according to claim **2**, wherein the output circuit comprises an electric motor presenting inductance to the receiver.

4. A device according to claim **3**, wherein the motor is a split phase motor.

5. A device according to claim **4**, wherein the motor is a drag motor having a non-magnetic conductive rotor.

6. A device according to claim **5**, wherein the motor has inertial damping.

7. A device according to claim **6**, wherein the motor has a shaft, a drag cup rotor on the shaft, and inertial damping is provided by a further drag cup on the shaft.

8. A device according to claim **6**, wherein the transmitter and receiver each comprise at least one of a Tesla coil and an autogenous pulsed abnormal glow discharge device.

9. A device according to claim **8**, wherein the transmitter and receiver both comprise Tesla coils, and further including a transmission cavity which comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively.

10. A device according to claim **9**, wherein the plates are parallel.

11. A device according to claim **9**, wherein the plates are concentric.

12. A device according to claim **9**, wherein at least the receiver comprises a Tesla coil driving a plasma reactor operating In PAGD (pulsed abnormal glow discharge) mode.

13. A device according to claim **12**, wherein the transmitter and receiver both comprise Tesla coils, and further Including a transmission cavity which comprises spaced plates connected respectively to the distal poles of the secondaries of Tesla coils incorporated in the transmitter and receiver respectively.

14. A device according to claim **1**, wherein the transmitter and receiver each comprise at least one of a Tesla coil and an autogenous pulsed abnormal glow discharge device.

15. A device according to claim **1** wherein a transmitter/receiver cavity is present and filled with an aqueous liquid.

16. A device for the conversion of massfree radiation into electrical or electrokinetic energy comprising a receiver of such radiation from a source of massfree electrical radiation having a damped wave component, the receiver being tuned to resonance with the damped wave frequency of the source, a co-resonant output circuit coupled into and extracting electrical or electrokinetic energy from the receiver, and at least one of a transmission cavity between the source and the receiver, a full-wave rectifier in the co-resonant output circuit, and an oscillatory pulsed glow discharge device incorporated in the co-resonant output circuit.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation application of U.S. patent application Ser. No. 11/358,264, filed on Feb. 21, 2006, which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more

around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100 volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected

to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the support structure;

providing a load with an electrical connection to the at least one collection device to passively draw current; and

powering a fuel cell between the support structure and the load, the powering performed with energy collected from the at least one collection device.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a collection fiber.

4. The method of claim **1**, wherein the collection device comprises a diode and a collection fiber and the diode is electrically connected between the collection fiber and the load.

5. The method of claim **1**, further comprising storing energy provided to the load.

6. The method of claim **5**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

7. The method of claim **3**, wherein the collection fiber comprises carbon fiber or graphite fiber.

8. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a diode electrically connected between the at least one collection device and the support structure.

9. The system of claim **8**, wherein the collection device comprises a diode.

10. The system of claim **8**, wherein the collection device comprises a collection fiber.

11. The system of claim **8**, wherein the collection device comprises a collection fiber and a diode electrically connected between the load and the collection fiber.

12. The system of claim **9**, wherein the diode is elevated relative to the ground level.

13. The system of claim **10**, wherein the collection fiber comprises a carbon fiber or a graphite fiber.

14. The system of claim **8**, further comprising:

a switch connected in series between the at least one collection device and the load; and

a capacitor connected in parallel with the switch and the load.

15. The system of claim **14**, wherein the switch comprises an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

16. The system of claim **15**, further comprising a transformer connected between the interrupter and the load.

17. The system of claim **8**, further comprising:

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

18. The system of claim **8**, further comprising a fuel cell between the support structure and the load.

19. The system of claim **18**, wherein the fuel cell produces hydrogen and oxygen.

20. A system of collecting energy comprising:

means for suspending at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to the means for suspending;

means for passively inducing current flow, the means for inducing current flow electrically connected to the means for suspending; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the at least one collection device and the means for inducing current flow.

21. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the collection device electrically connected to and suspended from the support structure, the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a switch connected in series between the at least one collection device and the load, the switch comprising an interrupter connected between the at least one collection device and the load, and wherein the interrupter comprises at least one of a fluorescent tube, a neon bulb, an AC light, and a spark gap.

22. The system of claim **21**, further comprising a transformer connected between the interrupter and the load.

23. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure, the collection device configured to passively draw current;

a load electrically connected to the at least one collection device;

a motor for providing power, the motor connected between the at least one collection device and the load; and

a generator powered by the motor.

24. A system of energy collection comprising:

a support structure;

at least one collection device with, in operation, microscopic points of a cross-section of the collection device exposed to the environment, the at least one collection device electrically connected to and suspended from the support structure the at least one collection device configured to passively draw current;

a load electrically connected to the at least one collection device; and

a fuel cell between the support structure and the load.

25. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

(57) ABSTRACT

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon and graphite are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air. Clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the atmosphere may include cosmic rays penetrating and interacting with the earth's atmosphere, and also the migration of ions, as well as other effects yet to be fully studied.

Some of the ionization in the lower atmosphere is caused by airborne radioactive substances, primarily radon. In most places of the world, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are primarily responsible for the atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an exemplary embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an exemplary embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an exemplary embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an exemplary embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an exemplary embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an exemplary embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an exemplary embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an exemplary embodiment of collecting energy with a collection fiber.

DETAILED DESCRIPTION

Electric charges on conductors reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An exemplary embodiment of this disclosure takes advantage of this

property, among others, to collect and use the energy generated by an electric field in the atmosphere. Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An exemplary embodiment utilizes carbon or graphite fibers for static electricity collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including aluminum or steel, but most notably, copper. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An exemplary embodiment of the collection fibers as collection device **130** includes graphite or carbon fibers. Graphite and carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, or graphite fibers are examples that demonstrate exemplary collection ability.

In at least one exemplary embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than **100** volts per meter under some conditions. When support wire **120** is suspended in the air at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An exemplary embodiment of the collection device comprises the diode with no collection fiber. A preferred embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restricts energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A-2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting. A plurality of diodes may be placed at any position on the support structure wire. A preferred embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2C** presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2D** presents another exemplary embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2E** provides another exemplary embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2F** presents another exemplary embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. A preferred embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2G** provides two supports as provided in FIG. **2F** such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and between multiple support structures. A plurality of diodes may be

placed at any position on the support structure. A preferred embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load.

Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an exemplary embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel. Non-limiting examples of spark gap **420** include mercury-reed switches and mercury-wetted reed switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground.

The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches and mercury-wetted reed switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit. Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents exemplary circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches and mercury-wetted reed switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.

Any process descriptions or blocks in flow charts should be understood as representing modules, segments, or portions of code which include one or more executable instructions for implementing specific logical functions or steps in the process, and alternate implementations are included within the scope of the preferred embodiment of the present disclosure in which functions may be executed out of order from that shown or discussed, including substantially concurrently or in reverse order, depending on the functionality involved, as would be understood by those reasonably skilled in the art of the present disclosure.

It should be emphasized that the above-described embodiments of the present disclosure, particularly, any "preferred" embodiments, are merely possible examples of implementations, merely set forth for a clear understanding of the principles of the disclosure. Many variations and modifications may be made to the above-described embodiment(s) of the disclosure without departing substantially from the spirit and principles of the disclosure. All such modifications and variations are intended to be included herein within the scope of this disclosure and the present disclosure and protected by the following claims.

Therefore, at least the following is claimed:

1. A method of collecting energy comprising:

suspending at least one collection device from a plurality of support structure wires elevated above a ground level, the collection device including a carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the support structure wire; and

providing a load with an electrical connection to the plurality of support structure wires to draw current.

2. The method of claim **1**, wherein the collection device comprises a diode.

3. The method of claim **1**, wherein the collection device comprises a diode electrically connected between the fiber and the load.

4. The method of claim **1**, further comprising storing energy provided to the load.

5. The method of claim **4**, wherein storing energy provided to the load comprises storing energy in a capacitor or an inductor.

6. The method of claim **2**, wherein the diode is elevated relative to the ground level.

7. A system of energy collection comprising:

a plurality of support structure wires elevated above ground level; at least one collection device including at least one carbon or graphite fiber that collects electrical enemy from the air and is electrically connected to the plurality of support structure wires; and

a load electrically connected to the plurality of support structure wires.

8. The system of claim **7**, wherein the collection device comprises a diode.

9. The system of claim **7**, wherein the collection device comprises a diode electrically connected between the load and the fiber.

10. The system of claim **8**, wherein the diode is elevated relative to the ground level.

11. The system of claim **7**, further comprising a diode electrically connected between the at least one collection device and the plurality of support structure wires.

12. The system of claim **7**, wherein the fiber comprises a first end and a second opposing end, and wherein the system further comprises a support structure connected to both ends of the fiber.

13. The system of claim **7**, comprising:

said at least one fiber including a plurality of collection fibers; a support frame having a top side and a bottom side; and a conducting connecting wire between the plurality of support structure wires and the support frame, wherein one end of each of a plurality of collection fibers is connected to the top side of the support frame, and the opposing end of each of a plurality of collection fibers is connected to the bottom side of the support frame.

14. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from a single point of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

15. The system of claim **7**, further comprising a rigid structure, the rigid structure comprising multiple supports extending outward from multiple points of the support structure, wherein each end of the fiber is connected to an end of the multiple supports.

16. The system of claim **14**, further comprising a plurality of rigid structures wherein said at least one fiber includes collection fibers connected between a plurality of the rigid structures.

17. The system of claim **7**, further comprising:

a switch connected in series between the plurality of support structure wires and the load; and

a capacitor connected in parallel with the switch and the load.

18. The system of claim **17**, wherein the switch comprises an interrupter connected between the plurality of support structure wires and the load.

19. The system of claim **18**, wherein the interrupter comprises one of a fluorescent tube, a neon bulb, an AC light, or a spark gap.

20. The system of claim **18**, further comprising a transformer connected between the interrupter and the load.

21. The system of claim **7**, further comprising:

a motor for providing power the motor connected between the plurality of support structure wires and the load; and

a generator powered by the motor.

22. The system of claim **7**, wherein the load comprises a spark gap in a container of fluid, and the load is used to produce a chemical reaction.

23. The system of claim **22**, wherein the fluid comprises water and the chemical reaction comprises the production of hydrogen and oxygen.

24. The system of claim **7**, further comprising a fuel cell between the plurality of support structure wires and the load.

25. The system of claim **7**, wherein the load comprises a fuel cell.

26. The system of claim **24**, wherein the fuel cell produces hydrogen and oxygen.

27. The system of claim **24**, further comprising a diode connected between the plurality of support structure wires and the fuel cell.

28. A system of collecting energy comprising:

means for suspending carbon or graphite collection fibers, the means elevated above a ground level, the collection fibers collecting electrical enemy from the air and electrically connected to the means for suspending collection fibers;

means for inducing current flow, the means for inducing current flow electrically connected to the means for suspending collection fibers; and

means for restricting the backflow of charge carriers, the means for restricting the backflow of charge carriers electrically connected between the collection fibers and the means for inducing current flow.

(57) **ABSTRACT**

An energy collection system may collect and use the energy generated by an electric field. Collection fibers are suspended from a support wire system supported by poles. The support wire system is electrically connected to a load by a connecting wire. The collection fibers may be made of any conducting material, but carbon, graphite, carbon/carbon, or a mixture thereof are preferred. Diodes may be used to restrict the backflow or loss of energy.

ENERGY COLLECTION

CROSS REFERENCE TO RELATED APPLICATION

This application is a continuation-in-part application of U.S. patent application Ser. No. 11/358,264,filed on Feb. 21, 2006,which is incorporated by reference herein.

TECHNICAL FIELD

The present disclosure is generally related to energy and, more particularly, is related to systems and methods for collecting energy.

BACKGROUND

The concept of fair weather electricity deals with the electric field and the electric current in the atmosphere propagated by the conductivity of the air or other gases. On Earth, clear, calm air carries an electrical current, which is the return path for thousands of lightening storms simultaneously occurring at any given moment around the Earth. For simplicity, this energy may be referred to as static electricity or static energy. FIG. **1** illustrates a weather circuit for returning the current from lightning, for example, back to ground **10**. Weather currents **20**, **30** return the cloud to ground current **40**.

In a lightening storm, an electrical charge is built up, and electrons arc across a gas, ionizing it and producing the lightening flash. As one of ordinary skill in the art understands, the complete circuit requires a return path for the lightening flash. The atmosphere is the return path for the circuit. The electric field due to the atmospheric return path is relatively weak at any given point because the energy of thousands of electrical storms across the planet are diffused over the atmosphere of the entire Earth during both fair and stormy weather. Other contributing factors to electric current being present in the Earth's atmosphere or above the surface or in the atmosphere of other planets may include cosmic rays penetrating and interacting with the planet's surface and/or atmosphere, and also the creation and migration of electrically charged ions, as well as other effects yet to be fully studied.

Some of the ionization near the surface of a planet or in the lower atmosphere is caused by airborne radioactive substances. In most places on Earth, ions are formed at a rate of 5-10 pairs per cubic centimeter per second at sea level. With increasing altitude, cosmic radiation causes the ion production rate to increase. In areas with high radon exhalation from the soil (or building materials), the rate may be much higher.

Alpha-active materials are also responsible for atmospheric ionization. Each alpha particle (for instance, from a decaying radon atom) will, over its range of some centimeters, create approximately 150,000-200,000 ion pairs.

While there is a large amount of usable energy available in the atmosphere of Earth, as well as above the surface or in the atmosphere of other bodies in space, a method or apparatus for efficiently collecting that energy has not been forthcoming. Therefore, a heretofore unaddressed need exists in the industry to address the aforementioned deficiencies and inadequacies.

SUMMARY

Embodiments of the present disclosure provide systems and methods for collecting energy. Briefly described in architecture, one embodiment of the system, among others, can be implemented by a support structure wire elevated above a ground level, at least one collection fiber electrically connected to the support structure wire; a load electrically connected to the support structure wire; and a diode electrically connected between the load and at least one collection fiber.

Embodiments of the present disclosure can also be viewed as providing methods for collecting energy. In this regard, one embodiment of such a method, among others, can be broadly summarized by the following steps: suspending at least one collection fiber from a support structure wire elevated above ground level, the fiber electrically connected to the support structure wire; providing a load with an electrical connection to the support structure wire to draw current; and providing a diode electrically connected between the collection fiber and the load.

Other systems, methods, features, and advantages of the present disclosure will be or become apparent to one with skill in the art upon examination of the following drawings and detailed description. It is intended that all such additional systems, methods, features, and advantages be included within this description, be within the scope of the present disclosure, and be protected by the accompanying claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Many aspects of the disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, emphasis instead being placed upon clearly illustrating the principles of the present disclosure. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. **1** is a circuit diagram of a weather energy circuit.

FIG. **2** is a perspective view of an example embodiment of many energy collectors elevated above ground by a structure.

FIG. **2**A is a side view of an energy collection fiber suspended from a support wire.

FIG. **2**B is a side view of an example embodiment of an energy collection fiber suspended from a support wire and with an additional support member.

FIG. **2**C is a perspective view of a support structure for multiple energy collection fibers.

FIG. **2**D is a side view of an example embodiment of a support structure for multiple energy collection fibers.

FIG. **2**E is a side view of a support structure for an energy collection fiber.

FIG. **2**F is a side view of an example embodiment of a support structure for an energy collection fiber.

FIG. **2**G is a side view of a support structure for multiple energy collection fibers.

FIG. **3** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

FIG. **4** is a circuit diagram of an example embodiment of a circuit for the collection of energy.

FIG. **5** is a circuit diagram of an example embodiment of an energy collection circuit for powering a generator and motor.

FIG. **6** is a circuit diagram of an example embodiment of a circuit for collecting energy and using it for the production of hydrogen and oxygen.

FIG. **7** is a circuit diagram of an example embodiment of a circuit for collecting energy, and using it for driving a fuel cell.

FIG. **8** is a circuit diagram of an example embodiment of a circuit for collecting energy.

FIG. **9** is a flow diagram of an example embodiment of collecting energy with a collection fiber.

FIG. **10** is a circuit diagram of an example embodiment of a circuit for collecting energy from a dual polarity source.

FIG. **11** is a system diagram of an example embodiment of an energy collection system connected to an automobile vehicle.

FIG. **12** is a system diagram of an example embodiment of an energy collection system connected to a lunar rover vehicle.

FIG. **13** is a system diagram of an example embodiment of an energy collection system comprising collection devices with a diode.

FIG. **14** is a system diagram of an example embodiment of an energy collection system comprising multiple legs of the system of FIG. **13**.

DETAILED DESCRIPTION

Methods for collecting ambient energy have been known since the early 1900's. However, due to low efficiency, those methods did not become commercially feasible. One of the primary advantages of the present disclosure over past arts is the efficiency achievable by utilizing the collection fibers disclosed herein to collect or harvest said ambient energy. Another primary advantage over past arts is the dual-polarity circuit (FIG. **10**) which makes use of both positive and negative ambient energy collected by the collection fibers to convert said energy into a steady positive electrical output.

Electric charges on conductors may reside entirely on the external surface of the conductors, and tend to concentrate more around sharp points and edges than on flat surfaces. Therefore, an electric field received by a sharp conductive point may be much stronger than a field received by the same charge residing on a large smooth conductive shell. An example embodiment of this disclosure takes advantage of this property, among others, to collect and use the energy generated by an electric field in the atmosphere or above the surface of a planet or heavenly body. “Energy” is not limited herein to energy generated by an electric field in the atmosphere. Energy as used herein may include any event, particle, or wave, including, but not limited to photons, protons, neutrons, electrons, neutrinos, leptons, muons, antimuons, mesons, baryons, positrons, bosons, gluons, gravitons, fermions, hadrons, ionic energy, gamma rays, cosmic rays, solar wind, quarks, energy generated by the triboelectric effect, convection lightning, and many other forms of energy known to one of ordinary skill in the art. These forms of energy, as well as others, may be present not only on Earth, but also on the moon of the Earth, on Mars, on Venus, and on other heavenly bodies and even in the relative vacuum of deep space.

Referring to collection system **100** presented in FIG. **2**, at least one collection device **130** may be suspended from a support wire system **120** supported by poles **110**. Collection device **130** may comprise a diode or a collection fiber individually, or the combination of a diode and a collection fiber. Support wire system **120** may be electrically connected to load **150** by connecting wire **140**. Supporting wire system **120** may be any shape or pattern. Also, conducting wire **140** may be one wire or multiple wires. The collection device **130** in the form of a fiber may comprise any conducting or non-conducting material, including carbon, graphite, Teflon, and metal. An example embodiment utilizes carbon fibers, graphite fibers, carbon/carbon fibers, or a mixture thereof for energy collection. Support wire system **120** and connecting wire **140** can be made of any conducting material, including, but not limited to, aluminum, steel, copper, and super-conductive material. Teflon may be added to said conductor as well, such as non-limiting examples of a Teflon impregnated wire, a wire with a Teflon coating, or Teflon strips hanging from a wire. Conducting wire **120**, **140**, and **200** may be bare wire, or coated with insulation as a non-limiting example. Wires **120** and **140** are a means of transporting the energy collected by collection device **130**.

An example embodiment of the collection fibers as collection device **130** includes graphite, carbon fibers, carbon/carbon fibers, or a mixture thereof. Graphite, carbon fibers, and carbon/carbon fibers, at a microscopic level, can have hundreds of thousands of points. Atmospheric electricity, energetic particles, or waves may be attracted to these points. If atmospheric electricity can follow two paths where one is a flat surface and the other is a pointy, conductive surface, the electrical charge will be attracted to the pointy, conductive surface. Generally, the more points that are present, the higher energy that can be gathered. Therefore, carbon, graphite fibers, carbon/carbon fibers, or a mixture thereof are examples that demonstrate example collection ability.

In at least one example embodiment, the height of support wire **120** may be an important factor. The higher that collection device **130** is from ground, the larger the voltage potential between collection device **130** and electrical ground. The electric field may be more than 100-300 volts per meter under some conditions on Earth. When support wire **120** is suspended at a particular altitude, wire **120** will itself collect a very small charge from ambient voltage. When collection device **130** is connected to support wire **120**, collection device **130** becomes energized and transfers the energy to support wire **120**.

A diode, not shown in FIG. **2**, may be connected in several positions in collection system **100**. A diode is a component that restricts the direction of movement of charge carriers. It allows an electric current to flow in one direction, but essentially blocks it in the opposite direction. A diode can be thought of as the electrical version of a check valve. The diode may be used to prevent the collected energy from discharging into the atmosphere through the collection fiber embodiment of collection device **130**. An example embodiment of the collection device comprises the diode with no collection fiber. Another embodiment, however, includes a diode at the connection point of a collection fiber to support system **120** such that the diode is elevated above ground. Multiple diodes may be used between collection device **130** and load **150**. Additionally, in an embodiment with multiple fibers, the diodes restrict energy that may be collected through one fiber from escaping through another fiber.

Collection device **130** may be connected and arranged in relation to support wire system **120** by many means. Some non-limiting examples are provided in FIGS. **2A**-**2G** using a collection fiber embodiment. FIG. **2A** presents support wire **200** with connecting member **210** for collection device **130**. Connection member **210** may be any conducting material allowing for the flow of electricity from connection device **130** to support wire **200**. Then, as shown in FIG. **2**, the support wire **200** of support system **120** may be electrically connected through conducting wire **140** to load **150**. A plurality of diodes may be placed at any position on the support structure wire. One embodiment places a diode at an elevated position at the connection point between a collection fiber embodiment of collection device **130** and connection member **210**. In an alternative embodiment, a diode is not placed between collection device **130** and connection member **210**.

Likewise, FIG. **2B** shows collection fiber **130** electrically connected to support wire **200** and also connected to support member **230**. Support member **230** may be connected to collection fiber **130** on either side. Support member **230** holds the fiber steady on both ends instead of letting it move freely. Support member **230** may be conducting or non-conducting.

A plurality of diodes may be placed at any position on the support structure wire. One embodiment places a diode at elevated position at the connection point between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**. In an alternative embodiment, a diode is not placed between collection fiber **130** and support wire **200** or between fiber **130**, support member **230**, and support wire **200**.

FIG. **2**C presents multiple collection fibers in a squirrel cage arrangement with top and bottom support members. Support structure **250** may be connected to support structure wire **200** by support member **240**. Structure **250** has a top **260** and a bottom **270** and each of the multiple collection fibers **130** are connected on one end to top **260** and on the other end to bottom **270**. A plurality of diodes may be placed at any position on support structure **250**. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support structure wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support structure wire **200**.

FIG. **2**D presents another example embodiment of a support structure with support members **275** in an x-shape connected to support structure wire **200** at intersection **278** with collection fibers **130** connected between ends of support members **275**. A plurality of diodes may be placed at any position on the support structure. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2**E provides another example embodiment for supporting collection fiber **130**. Collection fiber **130** may be connected on one side to support member **285**, which may be connected to support structure wire **200** in a first location and on the other side to support member **280**, which may be connected to support structure wire **200** in a second location on support structure wire **200**. The first and second locations may be the same location, or they may be different locations, even on different support wires. A plurality of diodes may be placed at any position on the support structure. One embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**. In an alternative embodiment, one or more diodes are not placed at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **2**F presents another example embodiment of a support for a collection fiber. Two support members **290** may support either side of a collection fiber and are connected to support wire **200** in a single point. A plurality of diodes may be placed at any position on the support structure. One embodiment places a diode at an elevated position at the connection point between collection fiber **130** and support wire **200**. In an alternative embodiment, a diode is not placed at an elevated position at the connection point between collection fiber **130** and support wire **200**.

FIG. **2**G provides two supports as provided in FIG. **2**F such that at least two support members **292**, **294** may be connected to support structure wire **200** in multiple locations and collection fibers **130** may be connected between each end of the support structures. Collection fibers **130** may be connected between each end of a single support structure and/or between multiple support structures. A plurality of diodes may be placed at any position on the support structure. One embodiment places one or more diodes at elevated positions at the connection point(s) between collection fiber **130** and support structure wire **200**. In an alternative embodiment, one or more diodes are not placed at elevated positions at the connection point(s) between collection fiber **130** and support wire **200**.

FIG. **3** provides a schematic diagram of storing circuit **300** for storing energy collected by one or more collection devices (**130** from FIG. **2**). Load **150** induces current flow. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. A plurality of diodes may be placed at any position in the circuit. Switch **330** may be electrically connected between load **150** and at least one collection device (**130** from FIG. **2**) to connect and disconnect the load. Capacitor **320** may be connected in parallel to the switch **330** and load **150** to store energy when switch **330** is open for delivery to load **150** when switch **330** is closed. Rectifier **340** may be electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. Rectifier **340** may be a full-wave or a half-wave rectifier. Rectifier **340** may include a diode electrically connected in parallel to load **150**, between the receiving end of switch **330** and ground. The direction of the diode of rectifier **340** is optional.

In an example embodiment provided in FIG. **4**, storage circuit **400** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **410**. If charging capacitor **410** is not used, then the connection to ground shown at capacitor **410** is eliminated. A plurality of diodes may be placed at any position in the circuit. Diode **310** may be electrically connected in series between one or more collection devices (**130** from FIG. **2**) and load **150**. Diode **440** may be placed in series with load **150**. The voltage from capacitor **410** can be used to charge spark gap **420** when it reaches sufficient voltage. Spark gap **420** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **420** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **420** arcs, energy will arc from one end of the spark gap **420** to the receiving end of the spark gap **420**. The output of spark gap **420** may be electrically connected in series to rectifier **450**. Rectifier **450** may be a full-wave or a half-wave rectifier. Rectifier **450** may include a diode electrically connected in parallel to transformer **430** and load **150**, between the receiving end of spark gap **420** and ground. The direction of the diode of rectifier **450** is optional. The output of rectifier **450** is connected to transformer **430** to drive load **150**.

FIG. **5** presents motor driver circuit **500**. One or more collection devices (**130** from FIG. **2**) are electrically connected to static electricity motor **510**, which powers generator **520** to drive load **150**. A plurality of diodes may be placed at any position in the circuit. Motor **510** may also be directly connected to load **150** to drive it directly.

FIG. **6** demonstrates a circuit **600** for producing hydrogen. A plurality of diodes may be placed at any position in the circuit. One or more collection devices (**130** from FIG. **2**) are electrically connected to primary spark gap **610**, which may be connected to secondary spark gap **640**. Non-limiting examples of spark gaps **610**, **640** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. Secondary spark gap **640** may be immersed in water **630** within container **620**. When secondary spark gap **640** immersed in water **630** is energized, spark gap **640** may produce bubbles of hydrogen and oxygen, which may be collected to be used as fuel or as components for breathable air, among other uses.

FIG. **7** presents circuit **700** for driving a fuel cell. A plurality of diodes may be placed at any position in the circuit.

Collection devices (**130** from FIG. **2**) provide energy to fuel cell **720** which drives load **150**. Fuel cell **720** may produce hydrogen and oxygen.

FIG. **8** presents example circuit **800** for the collection of energy. Storage circuit **800** stores energy from one or more collection devices (**130** from FIG. **2**) by charging capacitor **810**. If charging capacitor **810** is not used, then the connection to ground shown at capacitor **810** is eliminated. A plurality of diodes may be placed at any position in the circuit. The voltage from capacitor **810** can be used to charge spark gap **820** when it reaches sufficient voltage. Spark gap **820** may comprise one or more spark gaps in parallel or in series. Non-limiting examples of spark gap **820** include mercury-reed switches, mercury-wetted reed switches, open-gap spark gaps, and electronic switches. When spark gap **820** arcs, energy will arc from one end of spark gap **820** to the receiving end of spark gap **820**. The output of spark gap **820** may be electrically connected in series to rectifier **825**. Rectifier **825** may be a full-wave or a half-wave rectifier. Rectifier **825** may include a diode electrically connected in parallel to inductor **830** and load **150**, between the receiving end of spark gap **820** and ground. The direction of the diode of rectifier **825** is optional. The output of rectifier **825** is connected to inductor **830**. Inductor **830** may be a fixed value inductor or a variable inductor. Capacitor **870** may be placed in parallel with load **150**.

FIG. **9** presents a flow diagram of a method for collecting energy. In block **910**, one or more collection devices may be suspended from a support structure wire. In block **920**, a load may be electrically connected to the support structure wire to draw current. In block **930** a diode may be electrically connected between the support structure wire and the electrical connection to the load. In block **940**, energy provided to the load may be stored or otherwise utilized.
